

Modeling the risk of spread of EAB: Summer traffic is key

**Louis Iverson, Anantha Prasad,
Stephen Matthews & Matthew Peters**

Northern Research Station, USDA Forest
Service, Delaware, Ohio
The Ohio State University, Columbus, Ohio

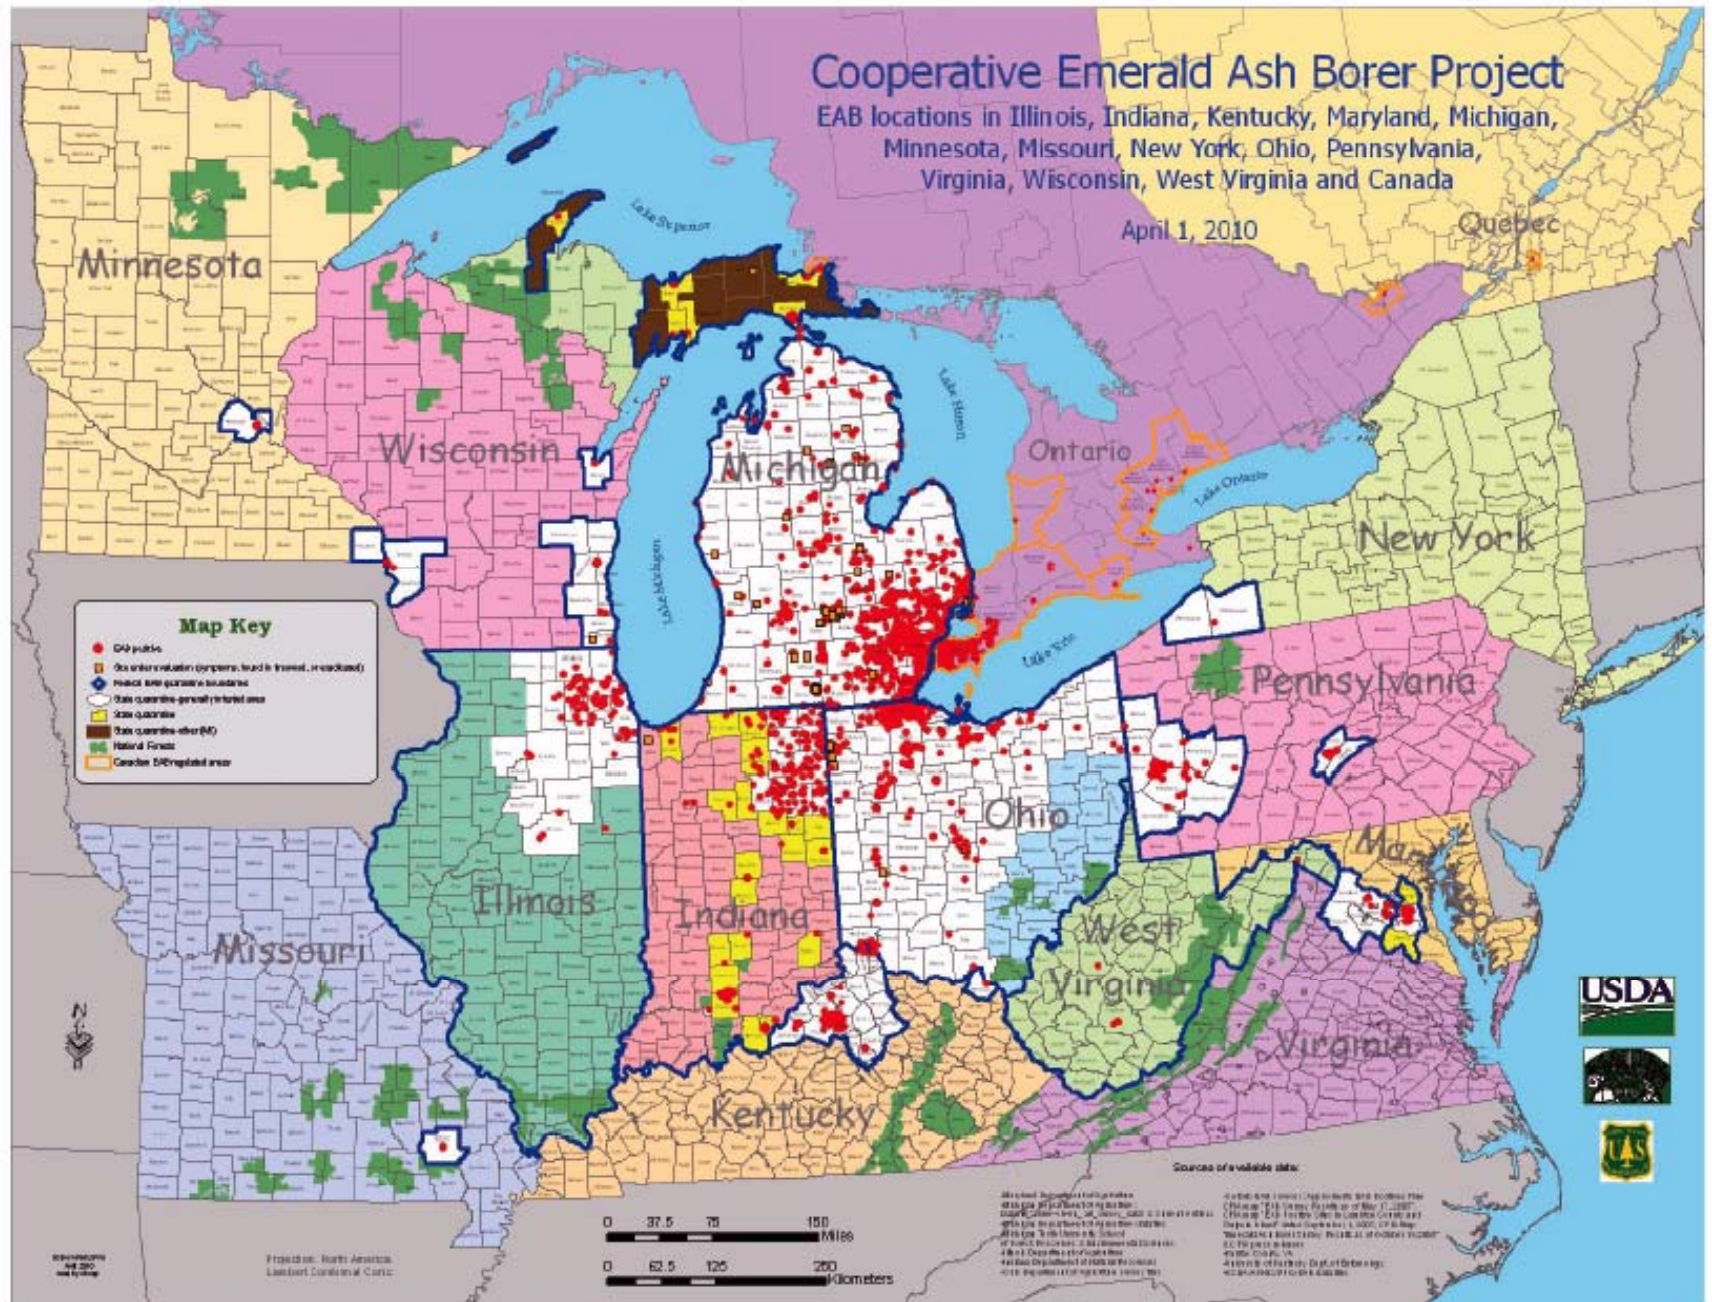

Our Role in EAB Research

- Quantification of visual parameters on street trees to assess ash health
- Estimating ash quantity in the eastern US
- Estimating EAB abundance by year
- Modeling spread risk

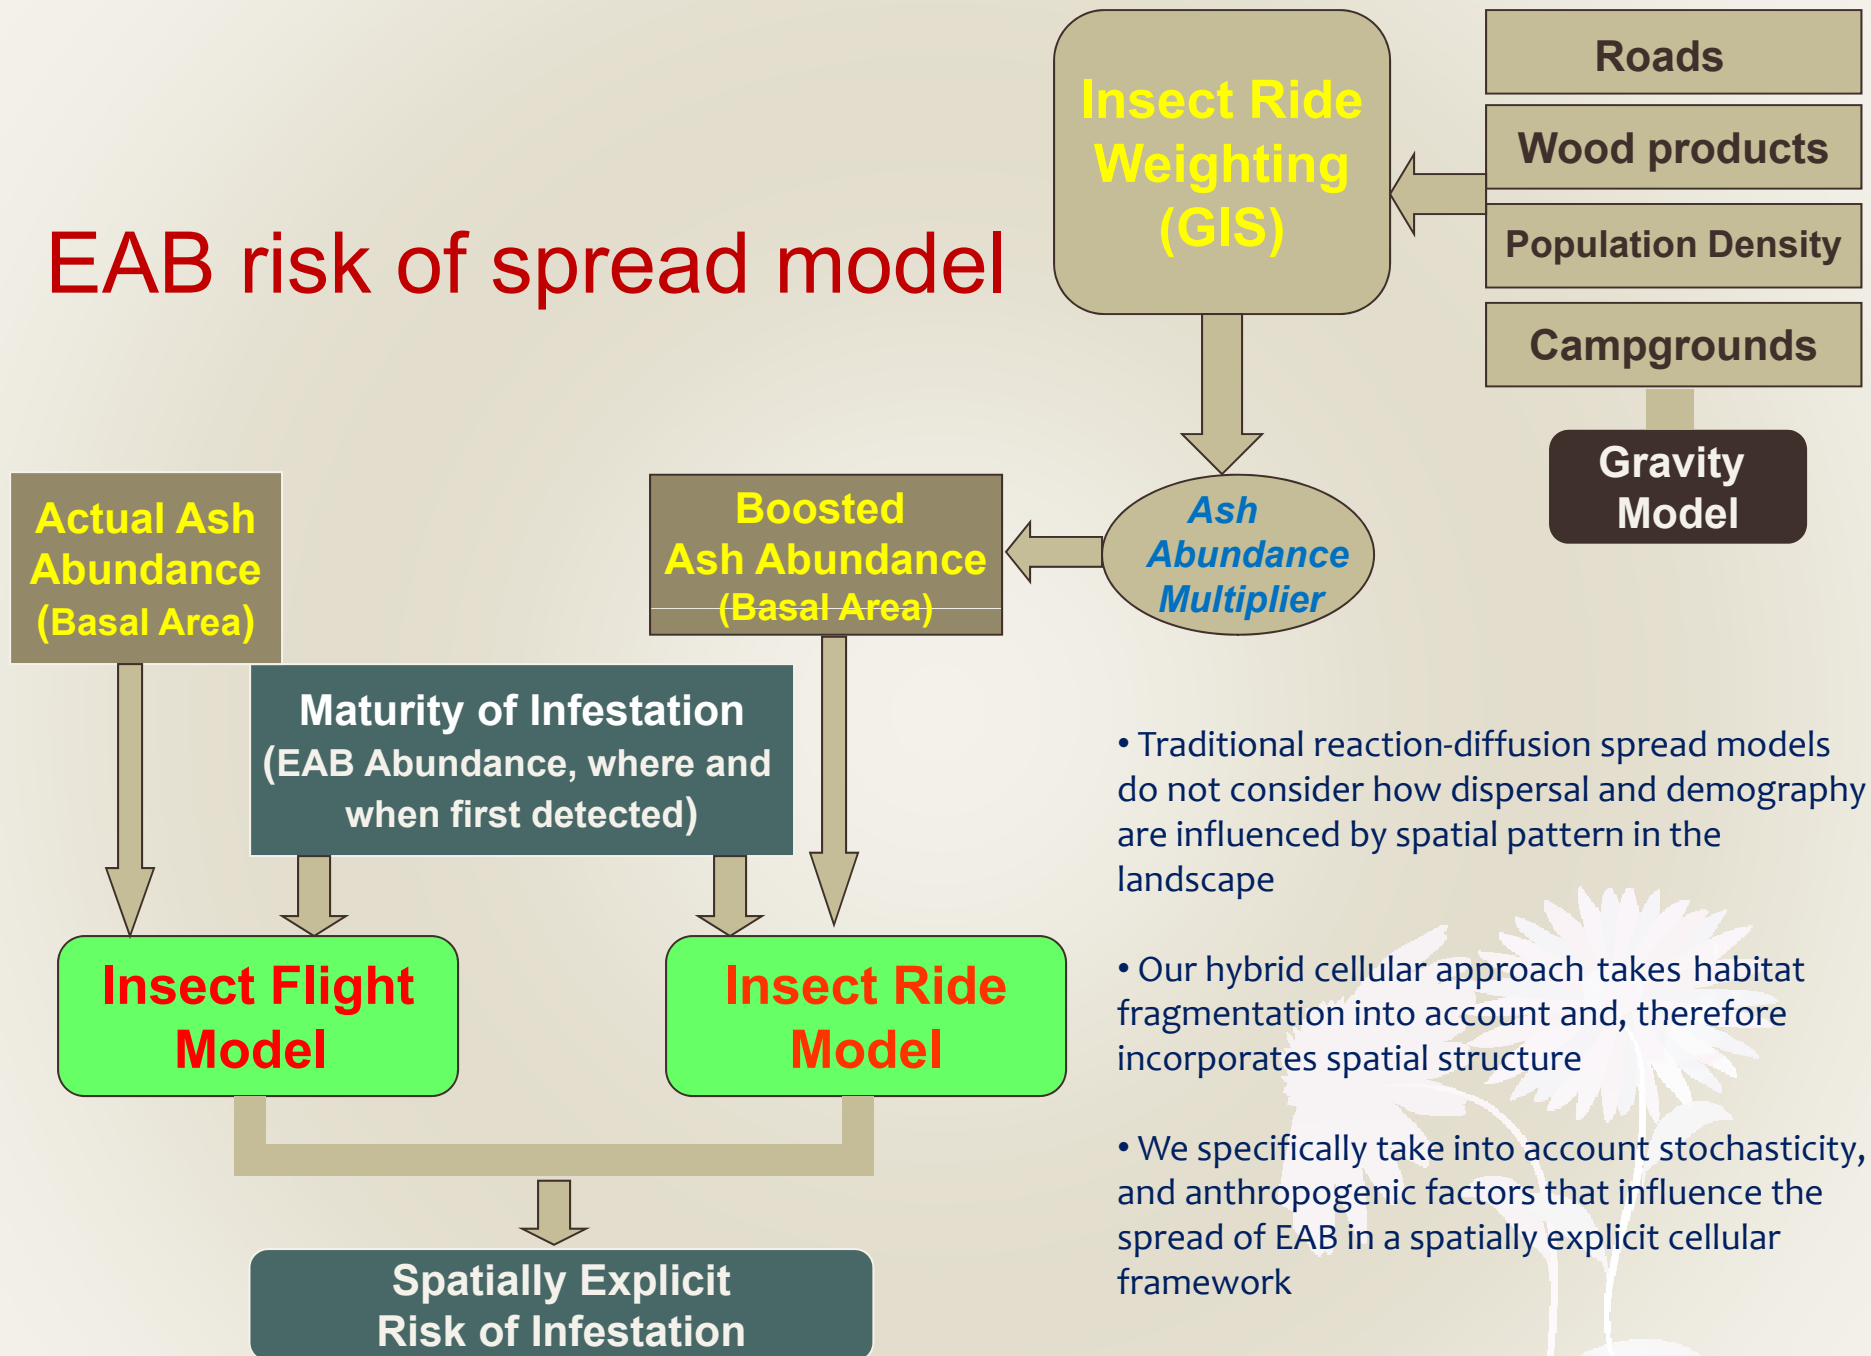

EAB locations in Illinois, Indiana, Kentucky, Maryland, Michigan, Minnesota, Missouri, New York, Ohio, Pennsylvania, Virginia, Wisconsin, West Virginia and Canada

Quebec

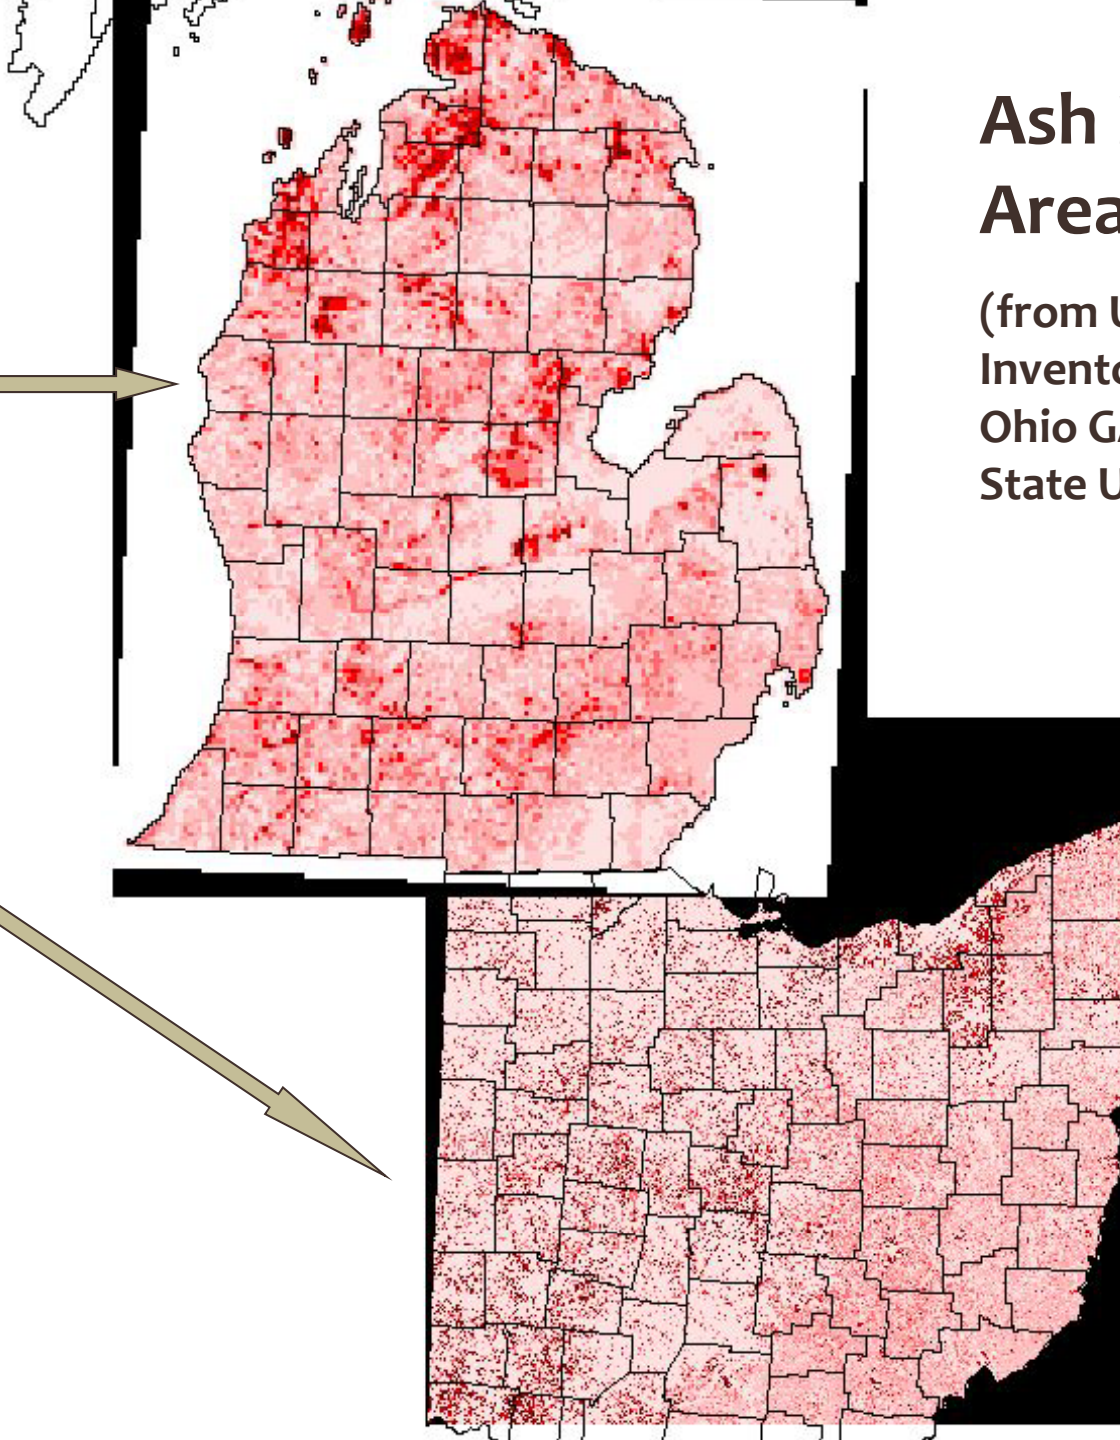

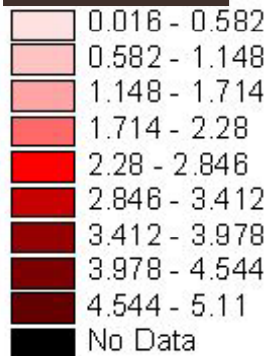

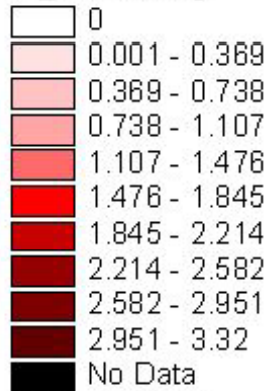

EAB risk of spread model

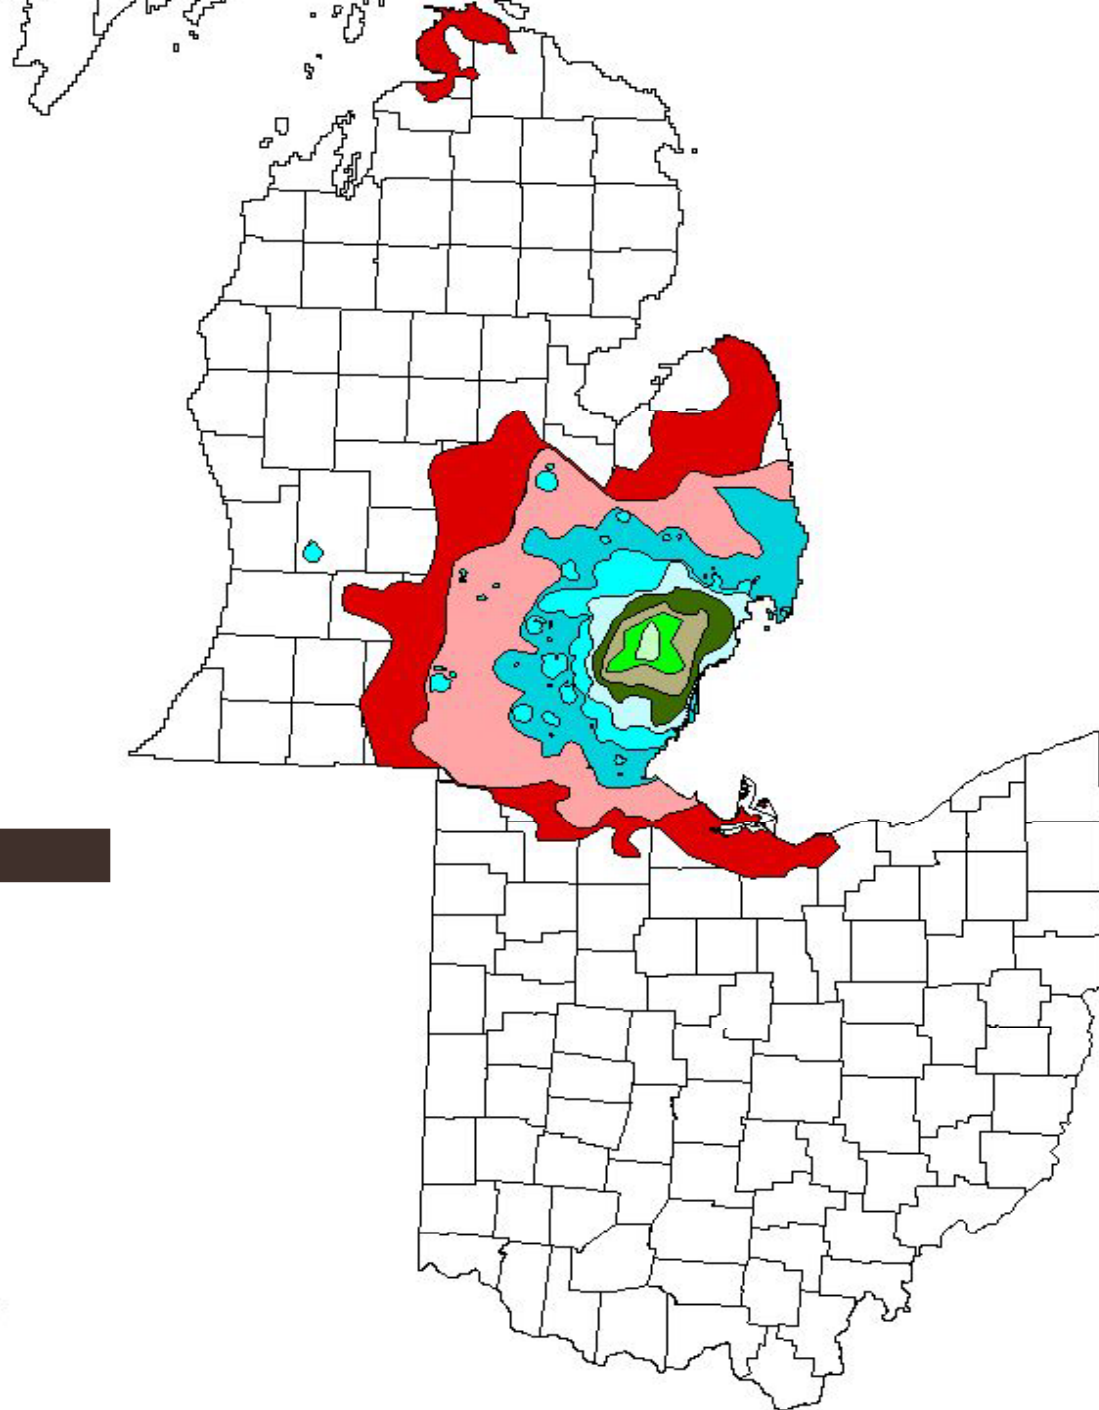

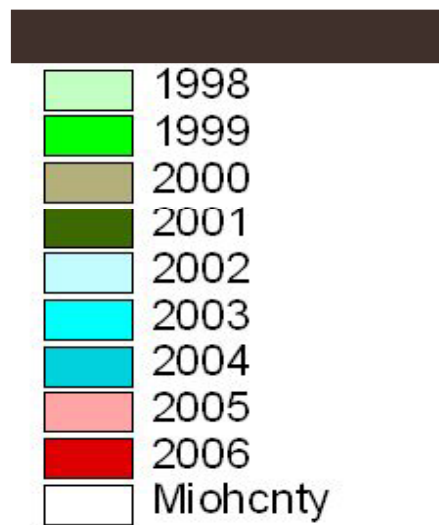

Ash Basal Area (m²/ha)

DISTRIB-SHIFT

Potential Distribution after 100 Years

Inputs:

- Habitat Quality (Ash BA)
- EAB Abundance

Output:

- Index of Risk (prob. of infest.)

Cell States:

- Occupied/Unoccupied
- Ash Quantity, BA

Habitat quality (ash basal area) of
unoccupied cell i and occupied cell j

$$P_{\text{colonization}, i} = \text{HQ}_i \left(\sum \text{HQ}_j \times F_j \times (C/D_{ij}^v) \right)$$

EAB abundance (0-1)
multiplier in **occupied cell**

colonization constant - used
to calibrate infestation rate
of approx. 20 km/yr

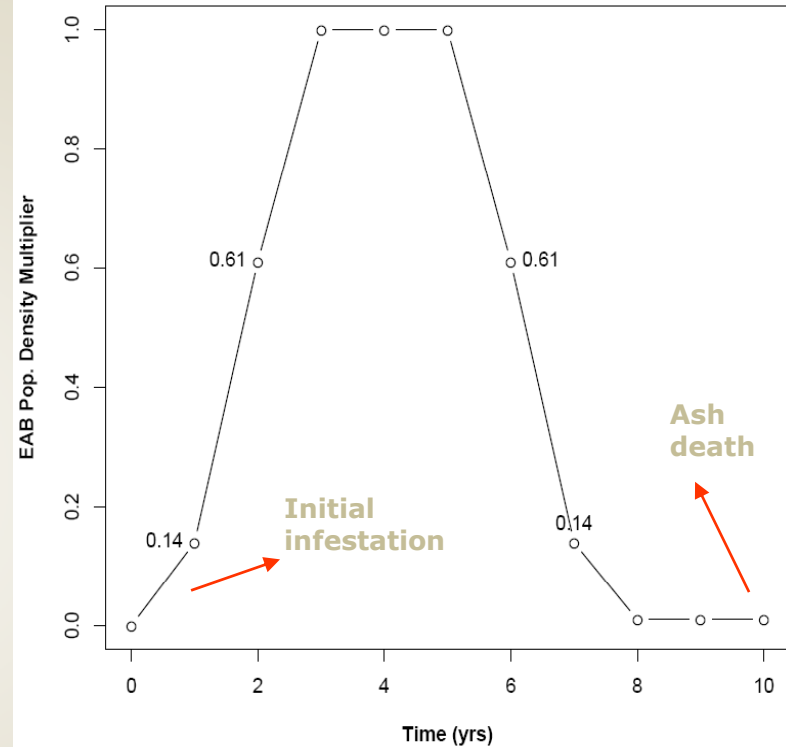

Distance between occupied
& unoccupied cells

Dispersal exponent, determines
the rate of decline with distance

cumulative probability of unoccupied cell i , becoming
infested with EAB

- Update EAB abundance and infestation probability each year (one generation) based on an assumption of an 10-year cycle between initial infestation and complete death of ash
- Once infested, the cell starts a 10 year EAB cycle until ash dies out
- The infestation probability (0-1) for each unoccupied cell is summed across all occupied cells within the search window at each generation. If cell gets > 1 , it is considered infested
- For cells with < 1 , a random number between 0-1 is chosen and the cell is declared infested if that number is $>$ than the cell sum, adding an element of stochasticity
- These newly infested cells contribute to the infestation prob. of unoccupied cells in the next generation

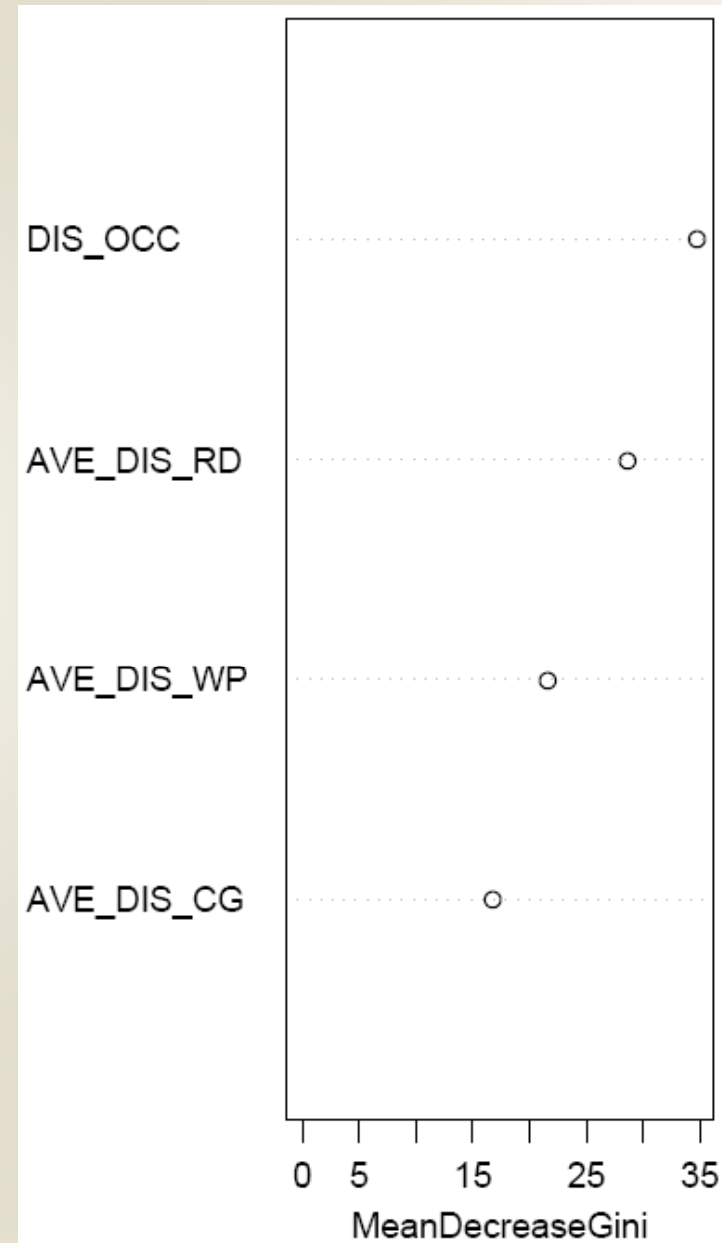

Updating EAB abundance

$$P_{\text{colonization}, i} = HQ_i \left(\sum HQ_j \times F_j \times (C/D_{i,j}^y) \right)$$

Insect ride weighting scheme

- Get average distance to roads, wood products, campgrounds and occupied (core area) zone from both the EAB positive trees and non-positive detection trees for the outlier (non-core) zone.
- Do a decision-tree based “RandomForest” statistical classification and evaluated the importance of these predictors
- Assess the significance of these factors for insect spread to obtain weighting guidelines.

A

Lake Erie

ROADS

- Analyzed Average Daily Densities (ADT) of Traffic of major roads in Ohio
- ADT values were scaled by buffered distance (1-2km) from each road – max score of 60

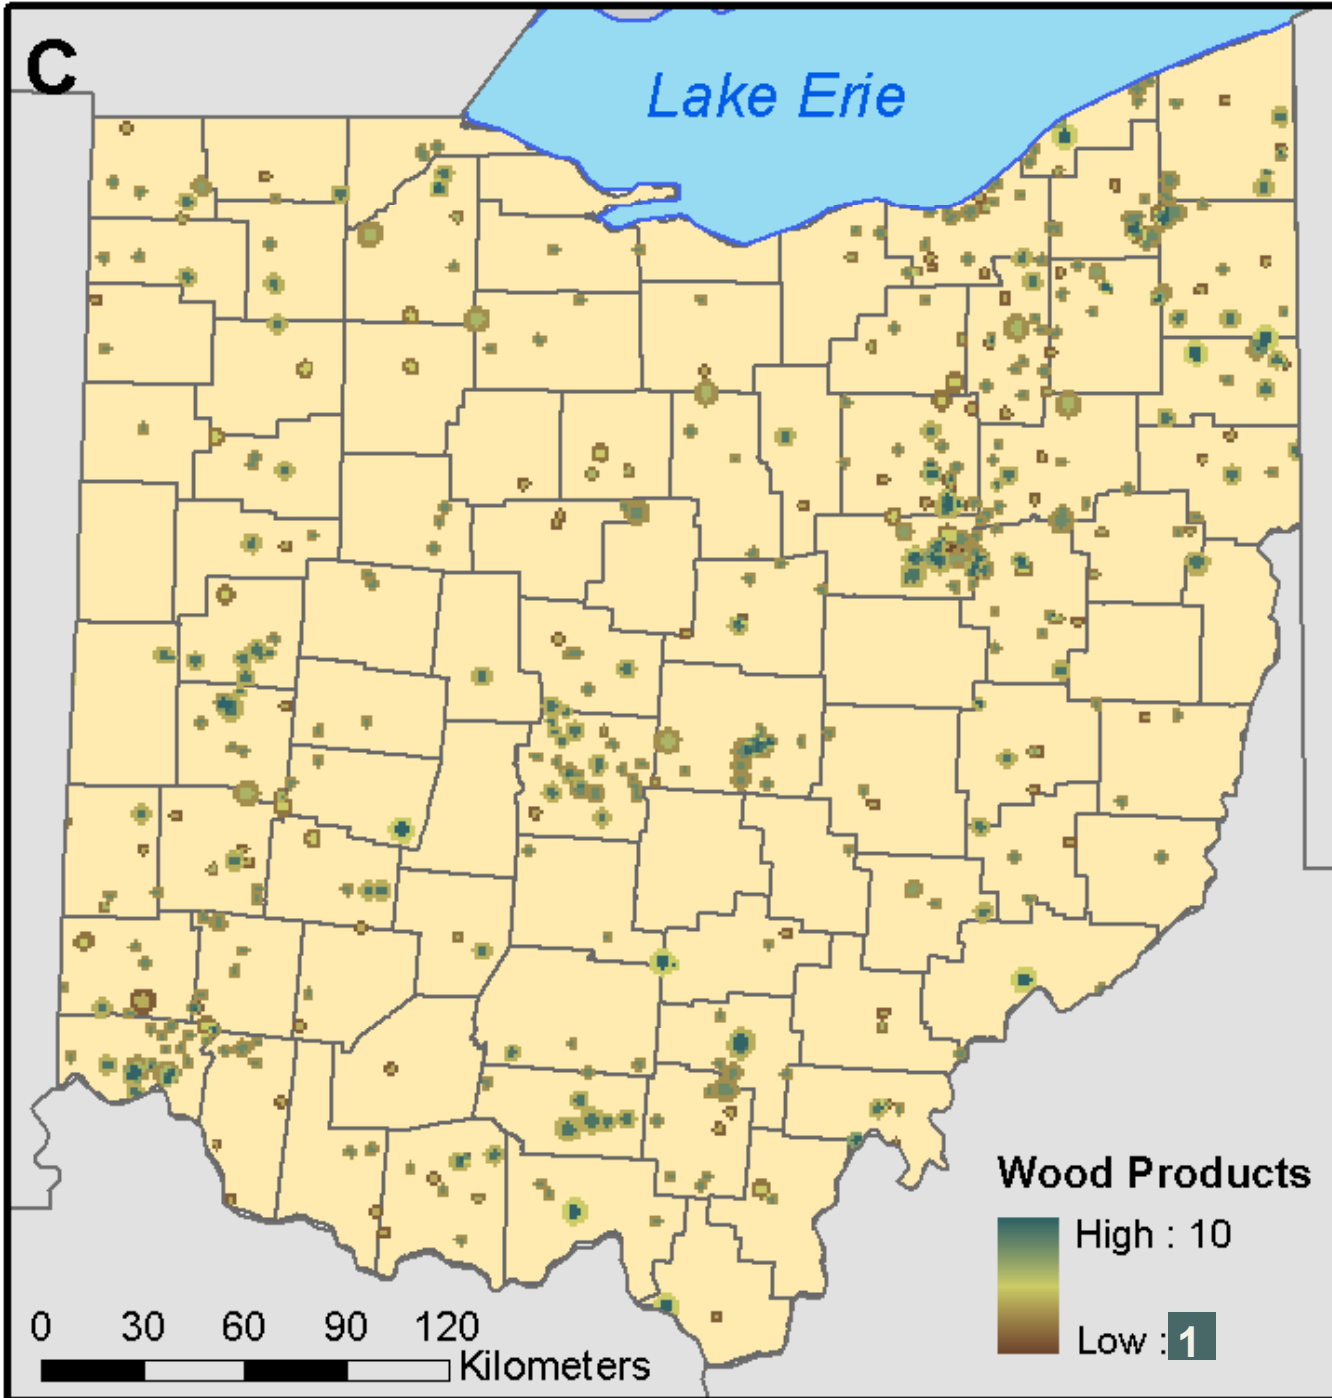

Average Daily Traffic

1 - 4	17 - 32
5 - 8	33 - 48
9 - 16	49 - 60

B

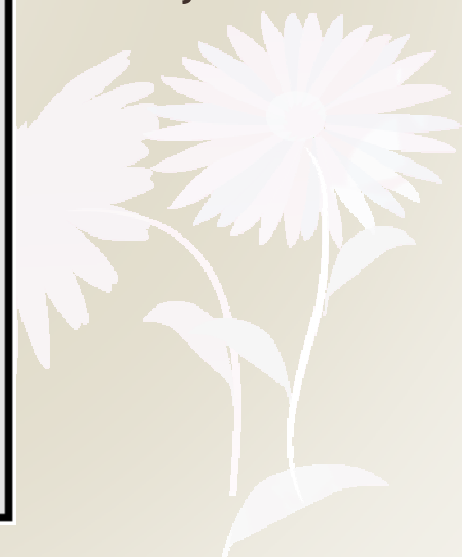

CAMPGROUNDS

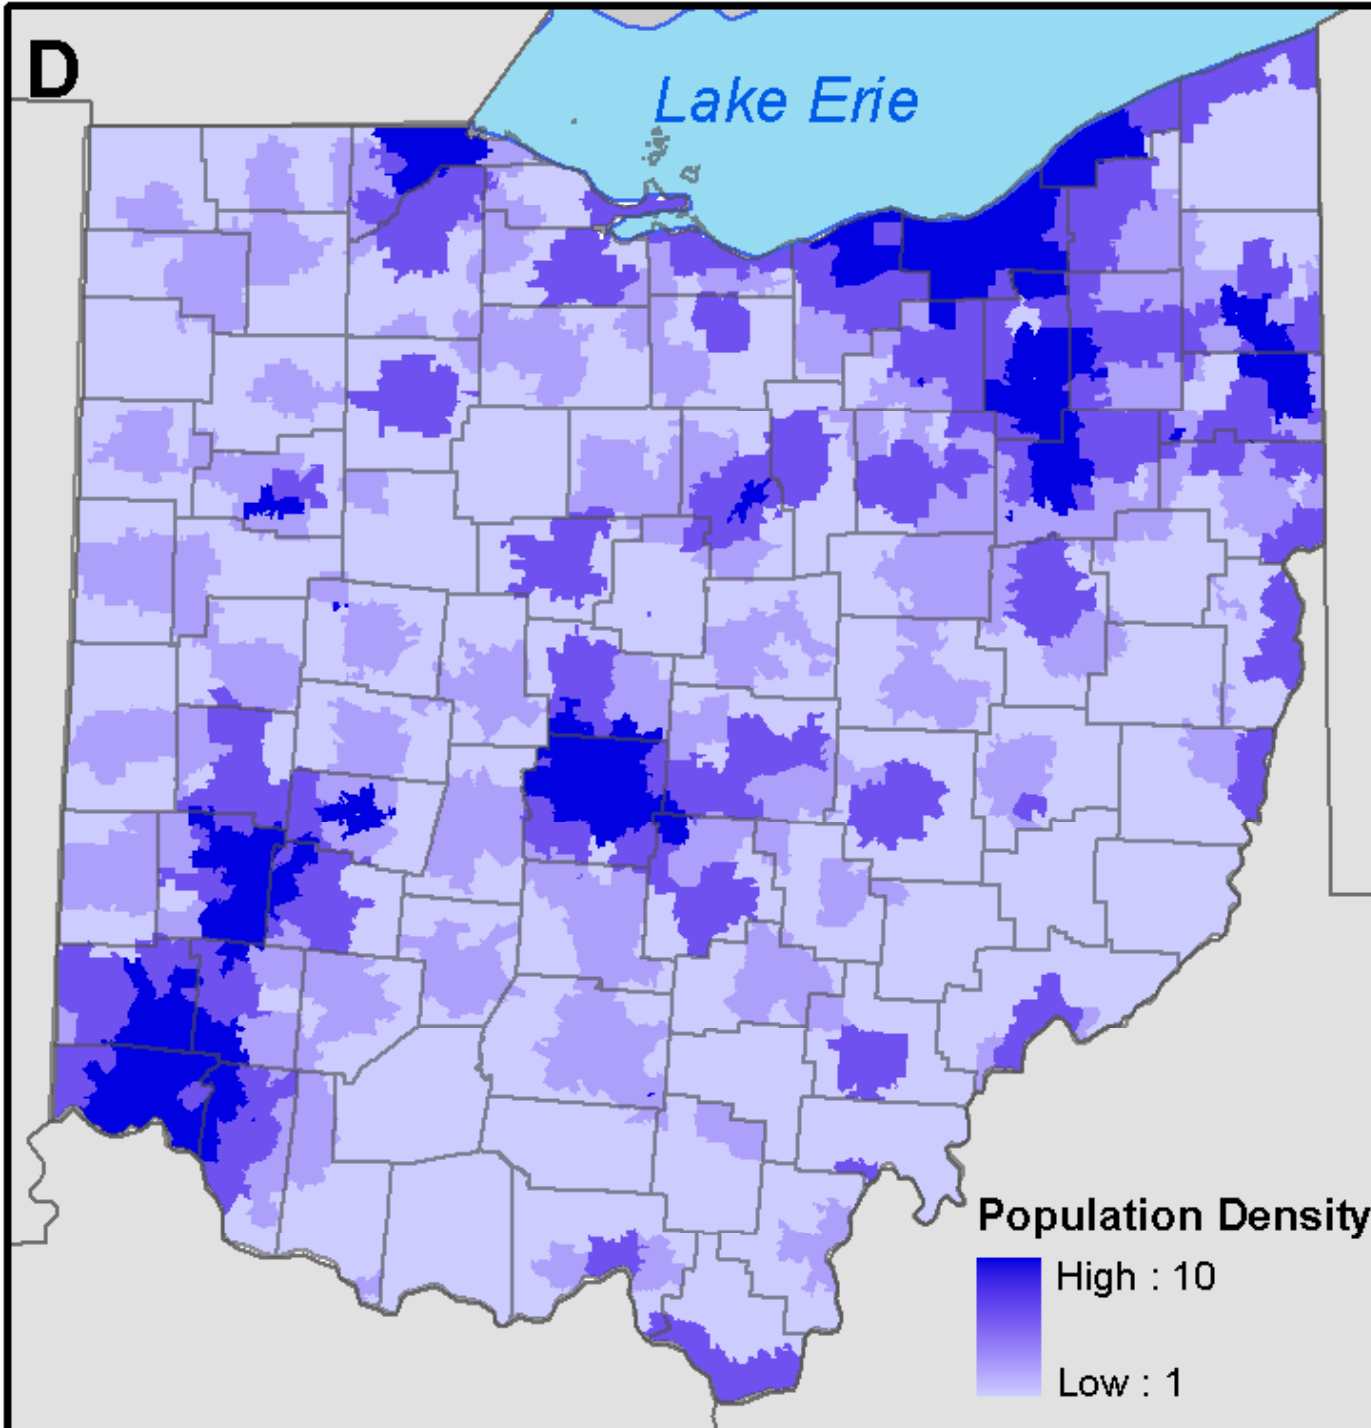

- Gravity model is used to assess people's movement to campgrounds (241) based on the distance and number of sites from EAB infested zip codes.
- We scaled the gravity model's weights by buffering the campgrounds (0-4km) based on the number of campsites – max weight of 20

C

WOOD PRODUCT INDUSTRIES

- Assessed industries based on the amount and status of ash used and scaled the weights by buffering sites (0-4km) based on the size of the facility.

D

POPULATION DENSITY

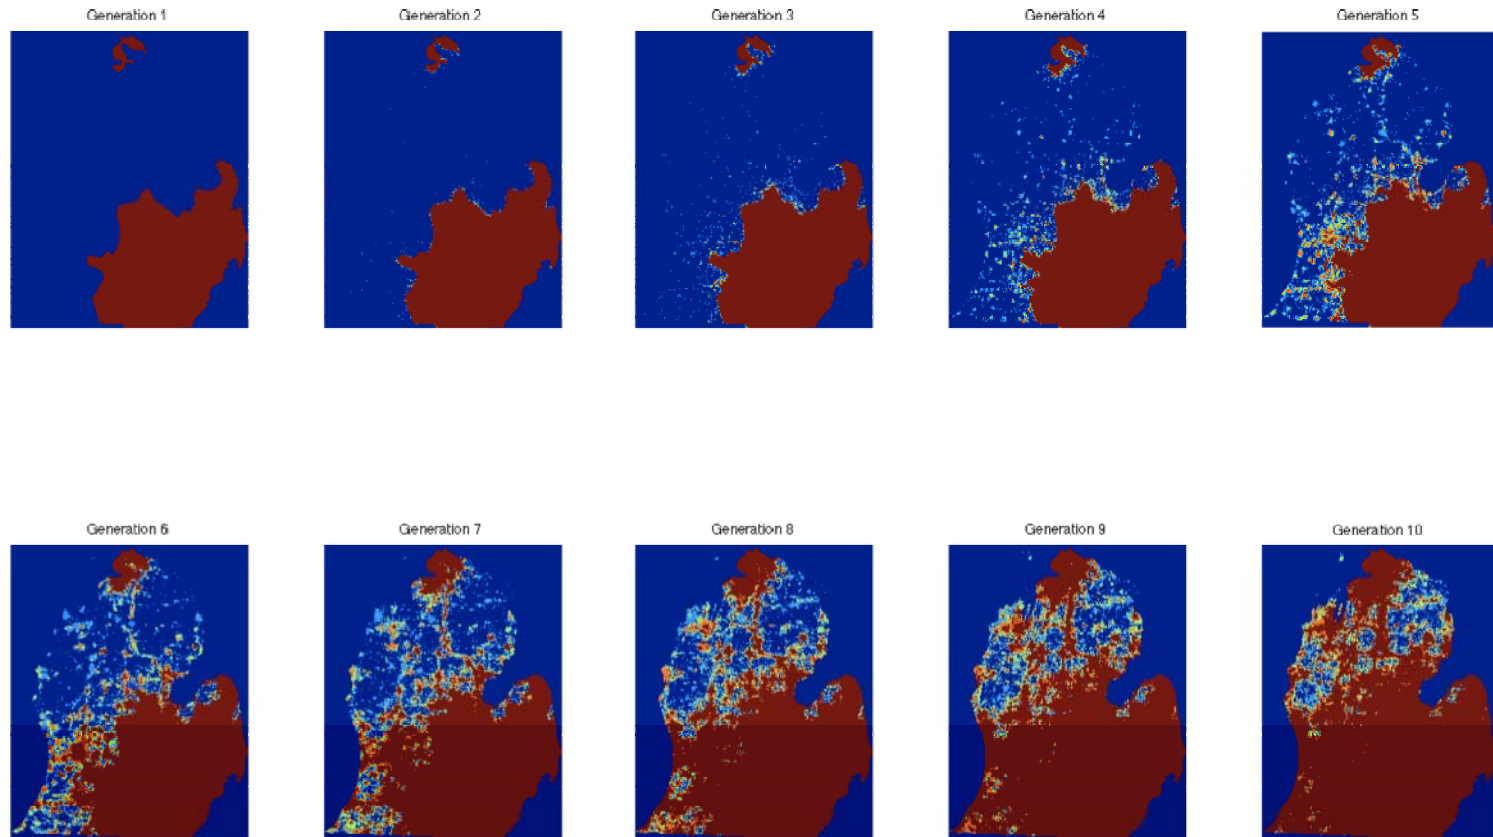

- Although road densities and ADT are good surrogates for pop. density, we used it to capture areas where they do not reflect human assisted movements.
- Max. score of 10

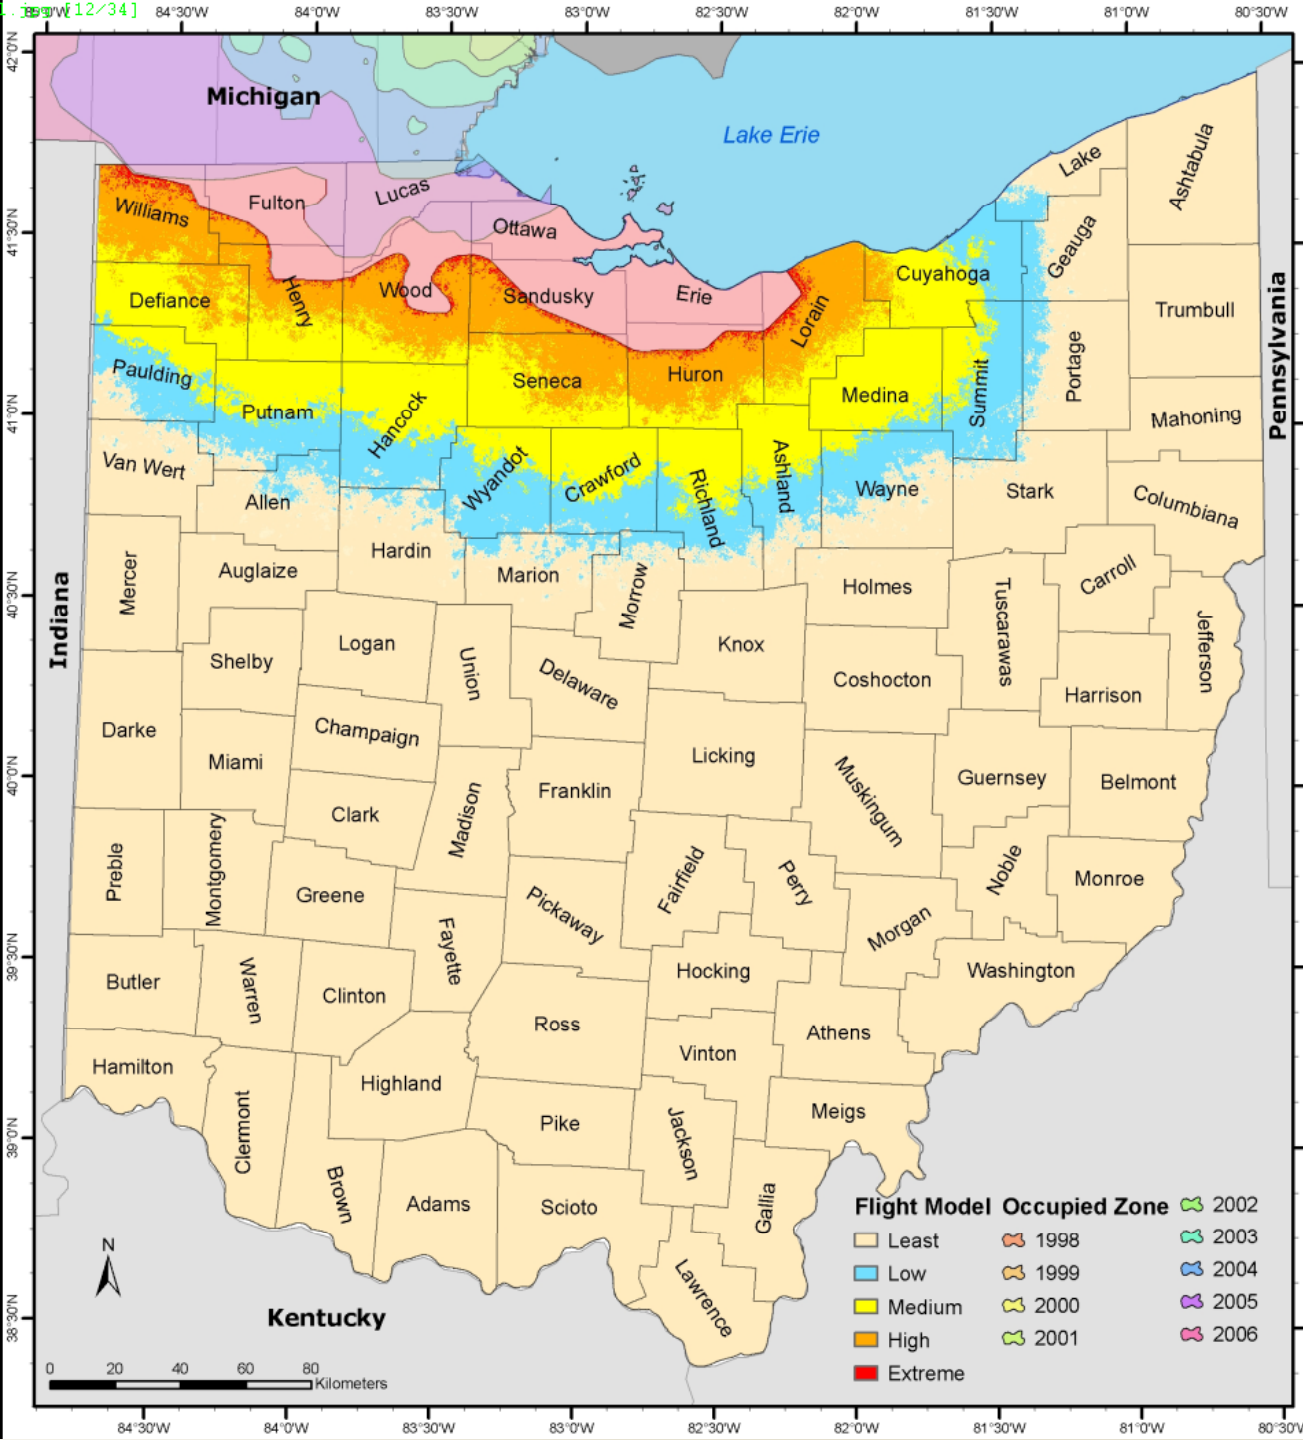

Quarantined counties in Ohio (in pink)

- Once county is quarantined, ash is legally allowed to be moved only within the county or to any other adjacent quarantined counties.
- We modelled the risk of spread within quarantined counties to be twice that of non-quarantined counties

MI spread for 10 generations

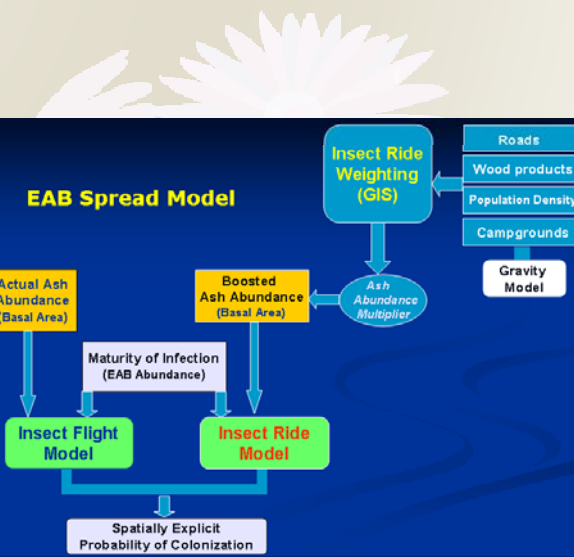

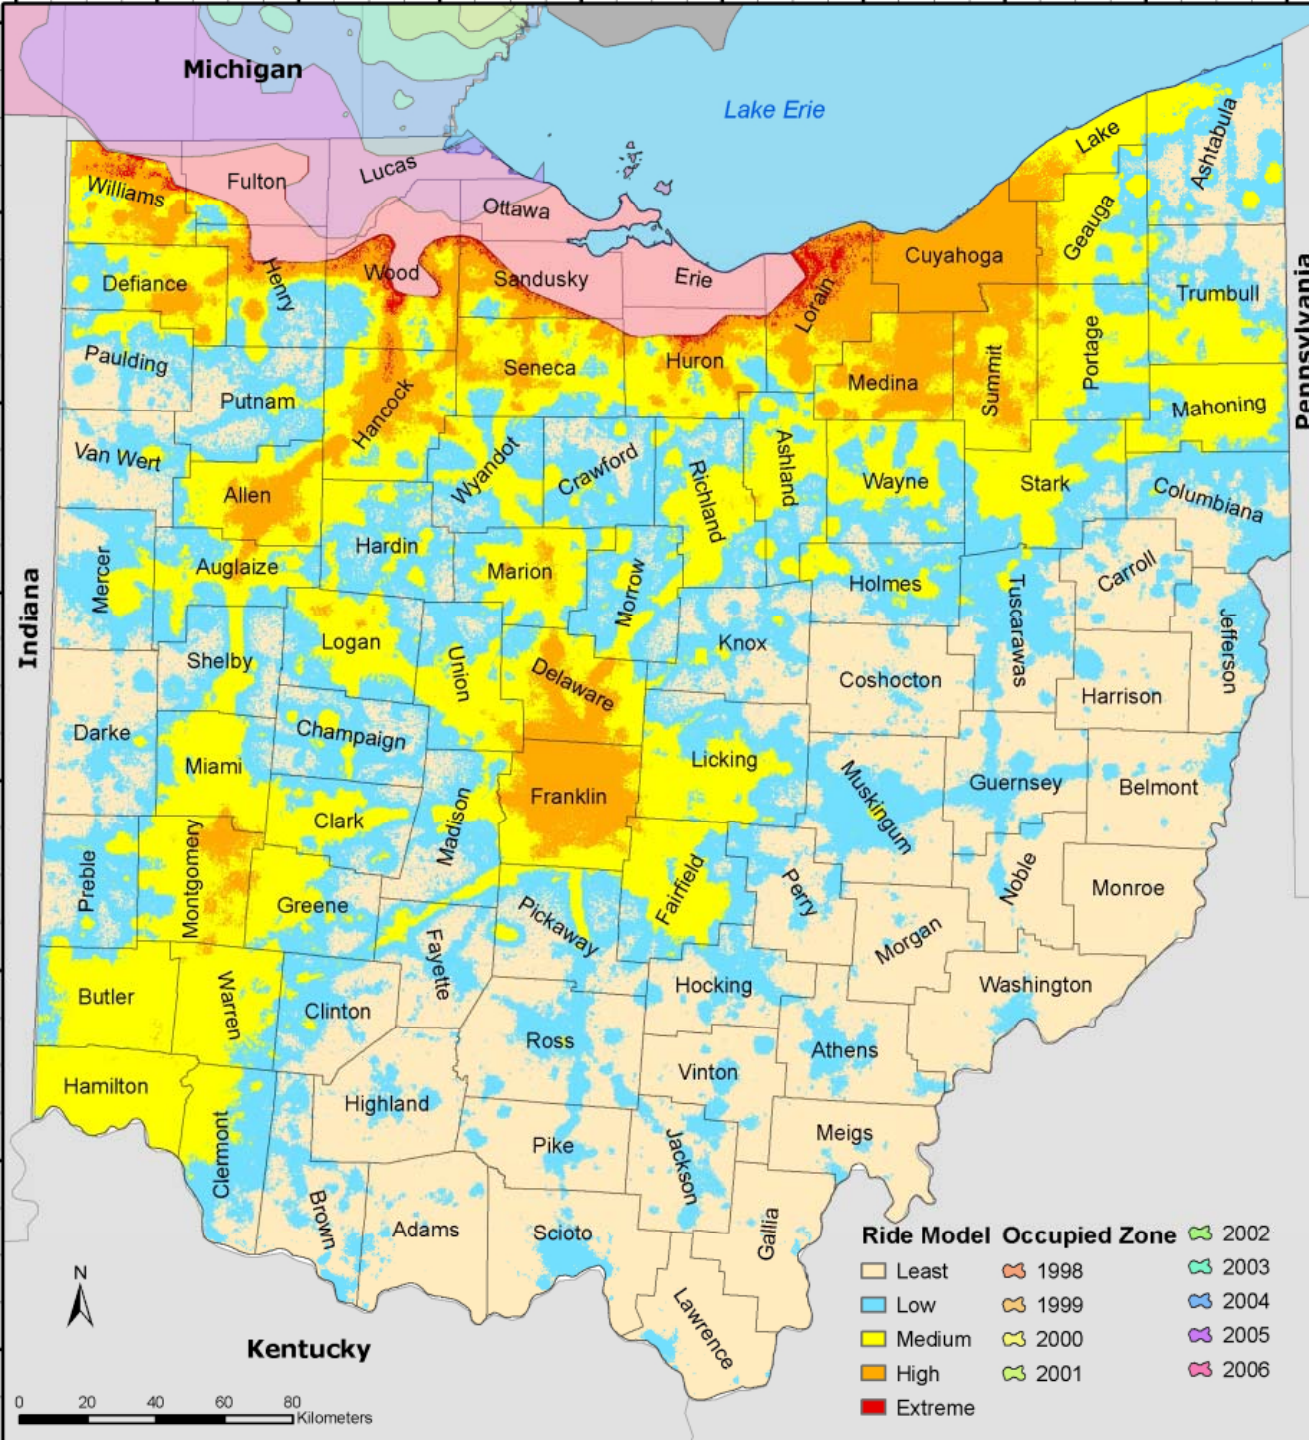

☀ Simulation results shown ran at Ohio Supercomputing Center

Insect flight model

40 km search window

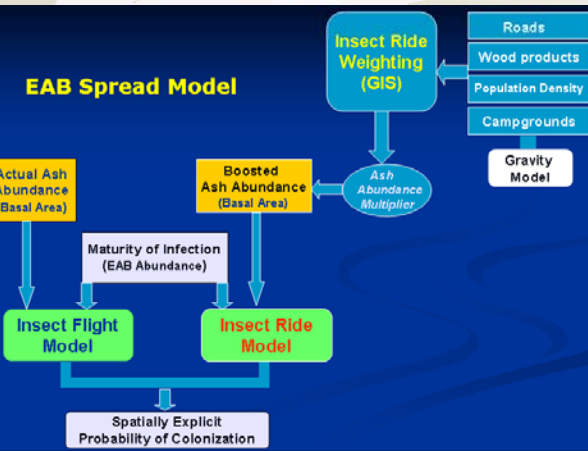

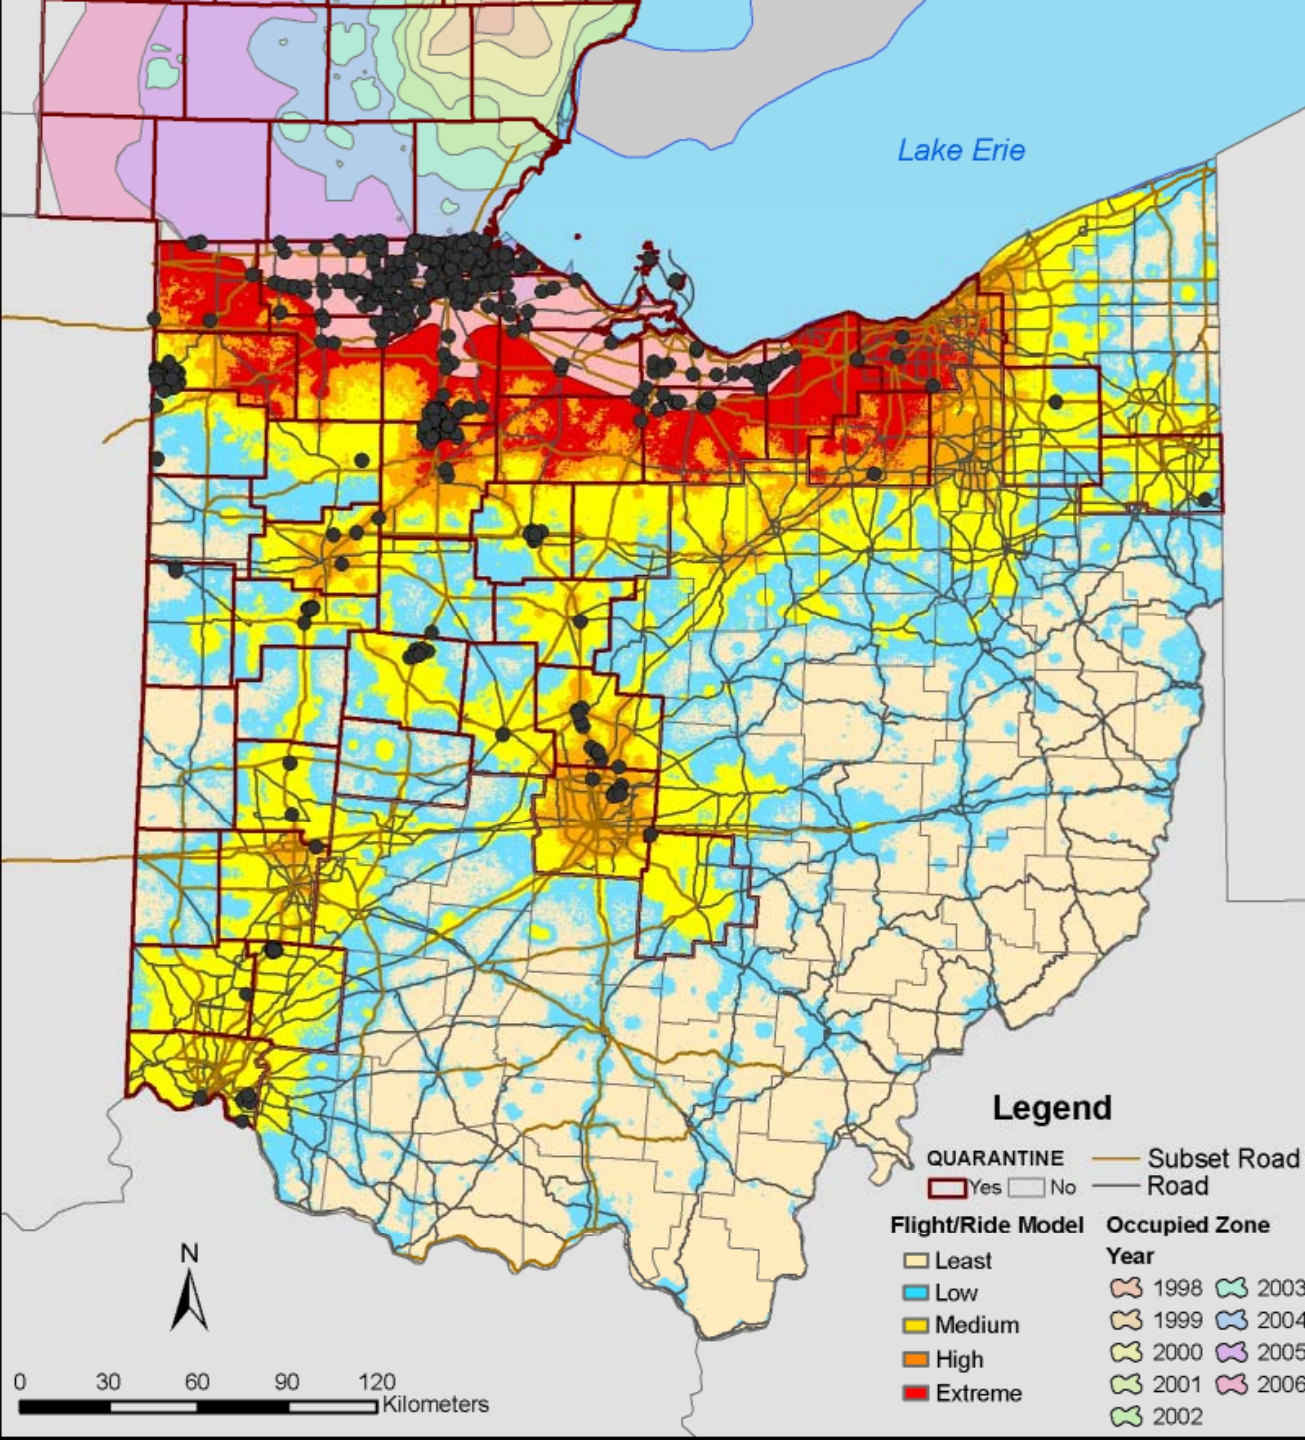

Insect ride model

Estimates Risk of Spread away from the “core “ of occupied zone

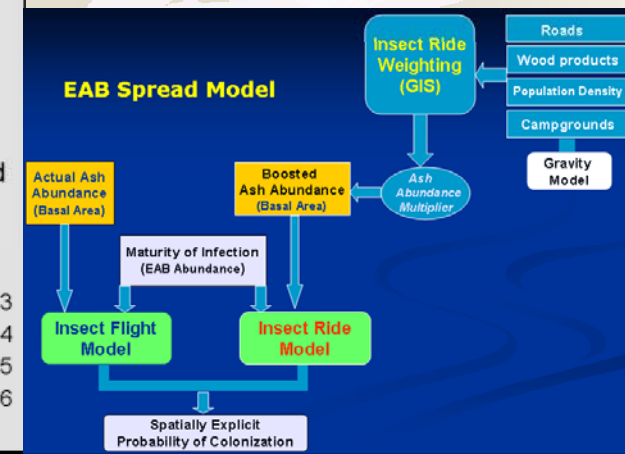

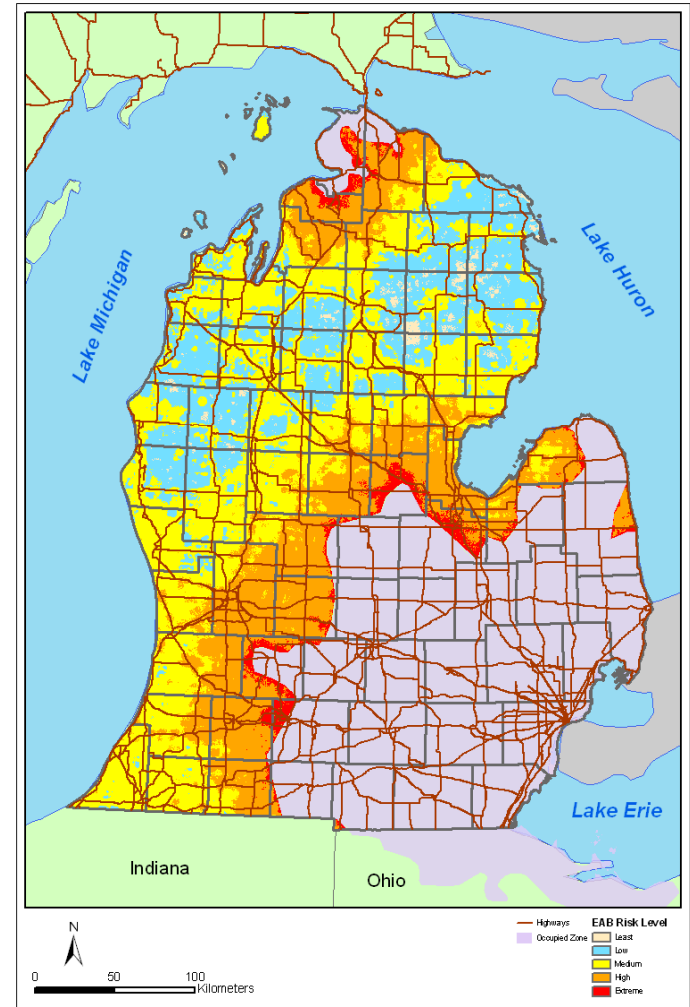

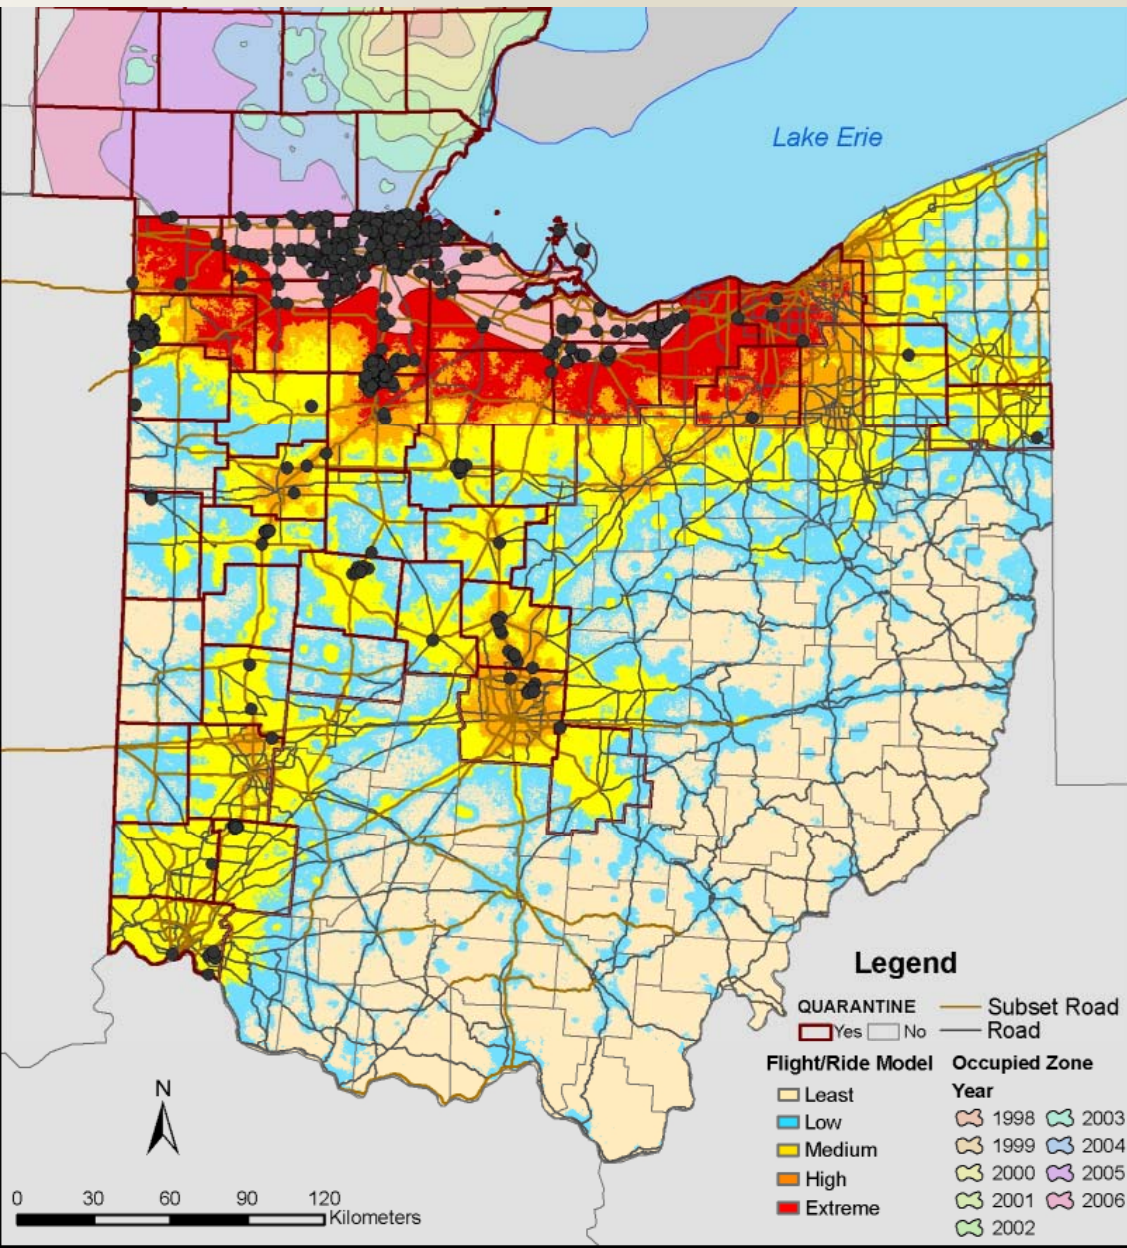

Combined
flight + ride
risk map

+

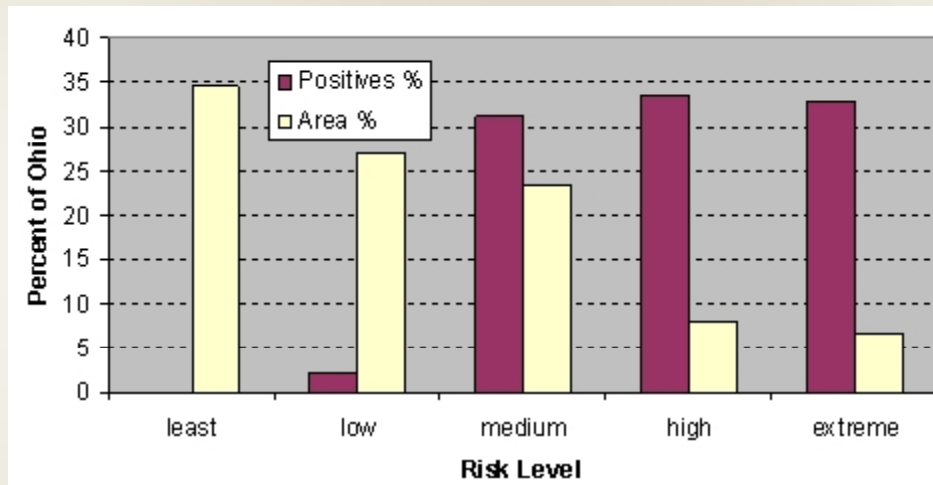

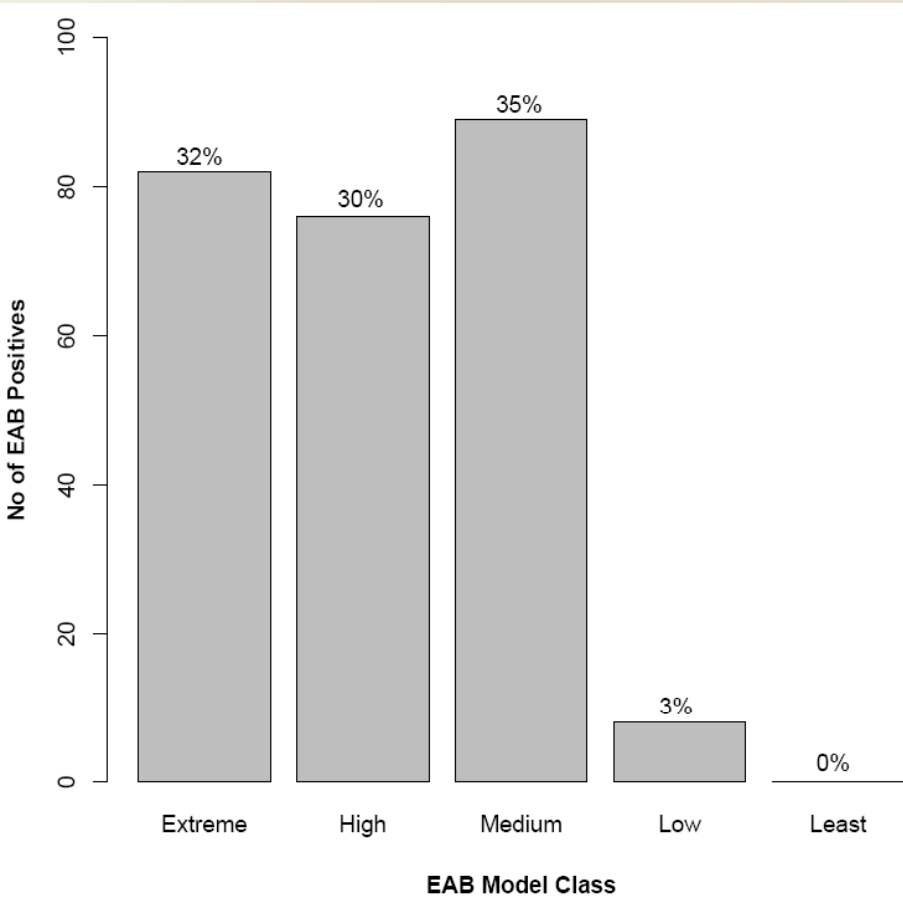

EAB positives

Combined Flight + Ride Risk Map

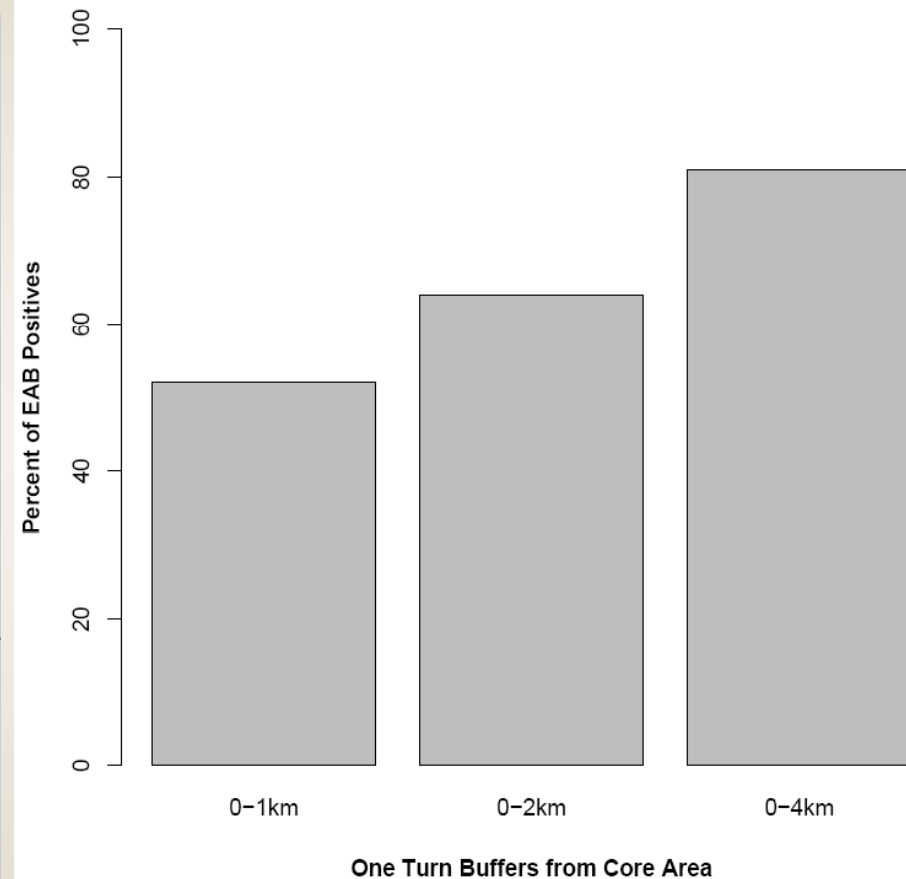

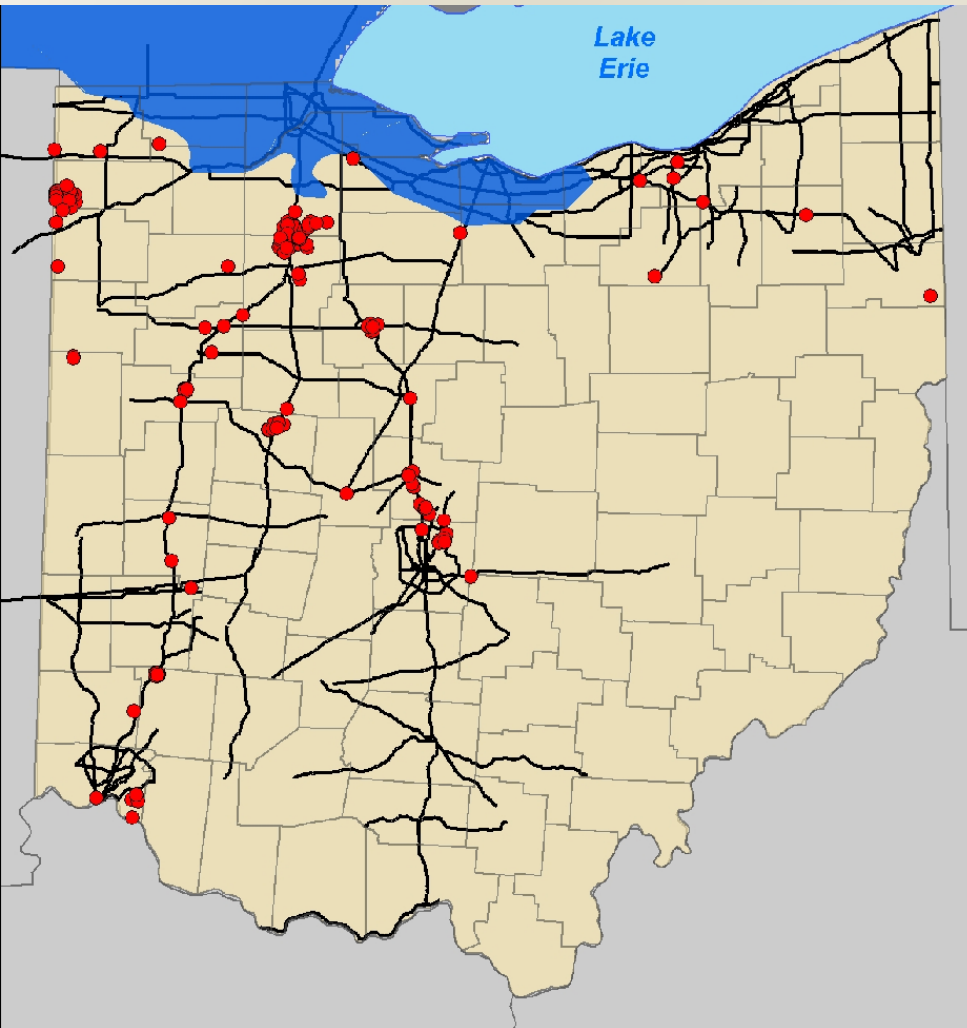

Promising Aspects of Model Results (not validation!)

**62% of positives in Extreme & Hi class
cover only 14% of the state**

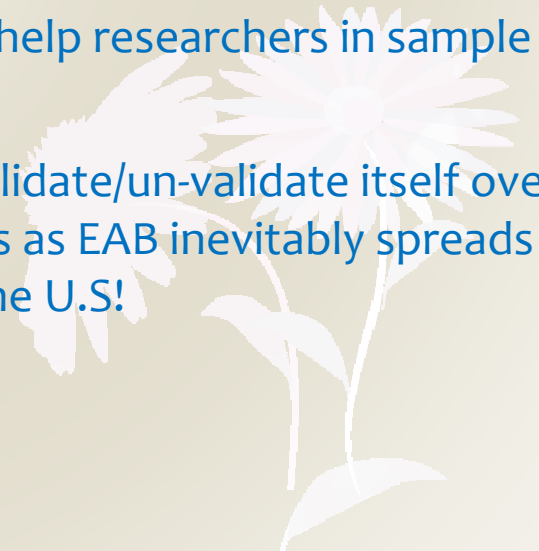

Importance of Road Network

Subset of Roads represent only 35% of total road length used in modeling

Validation vs. Utility

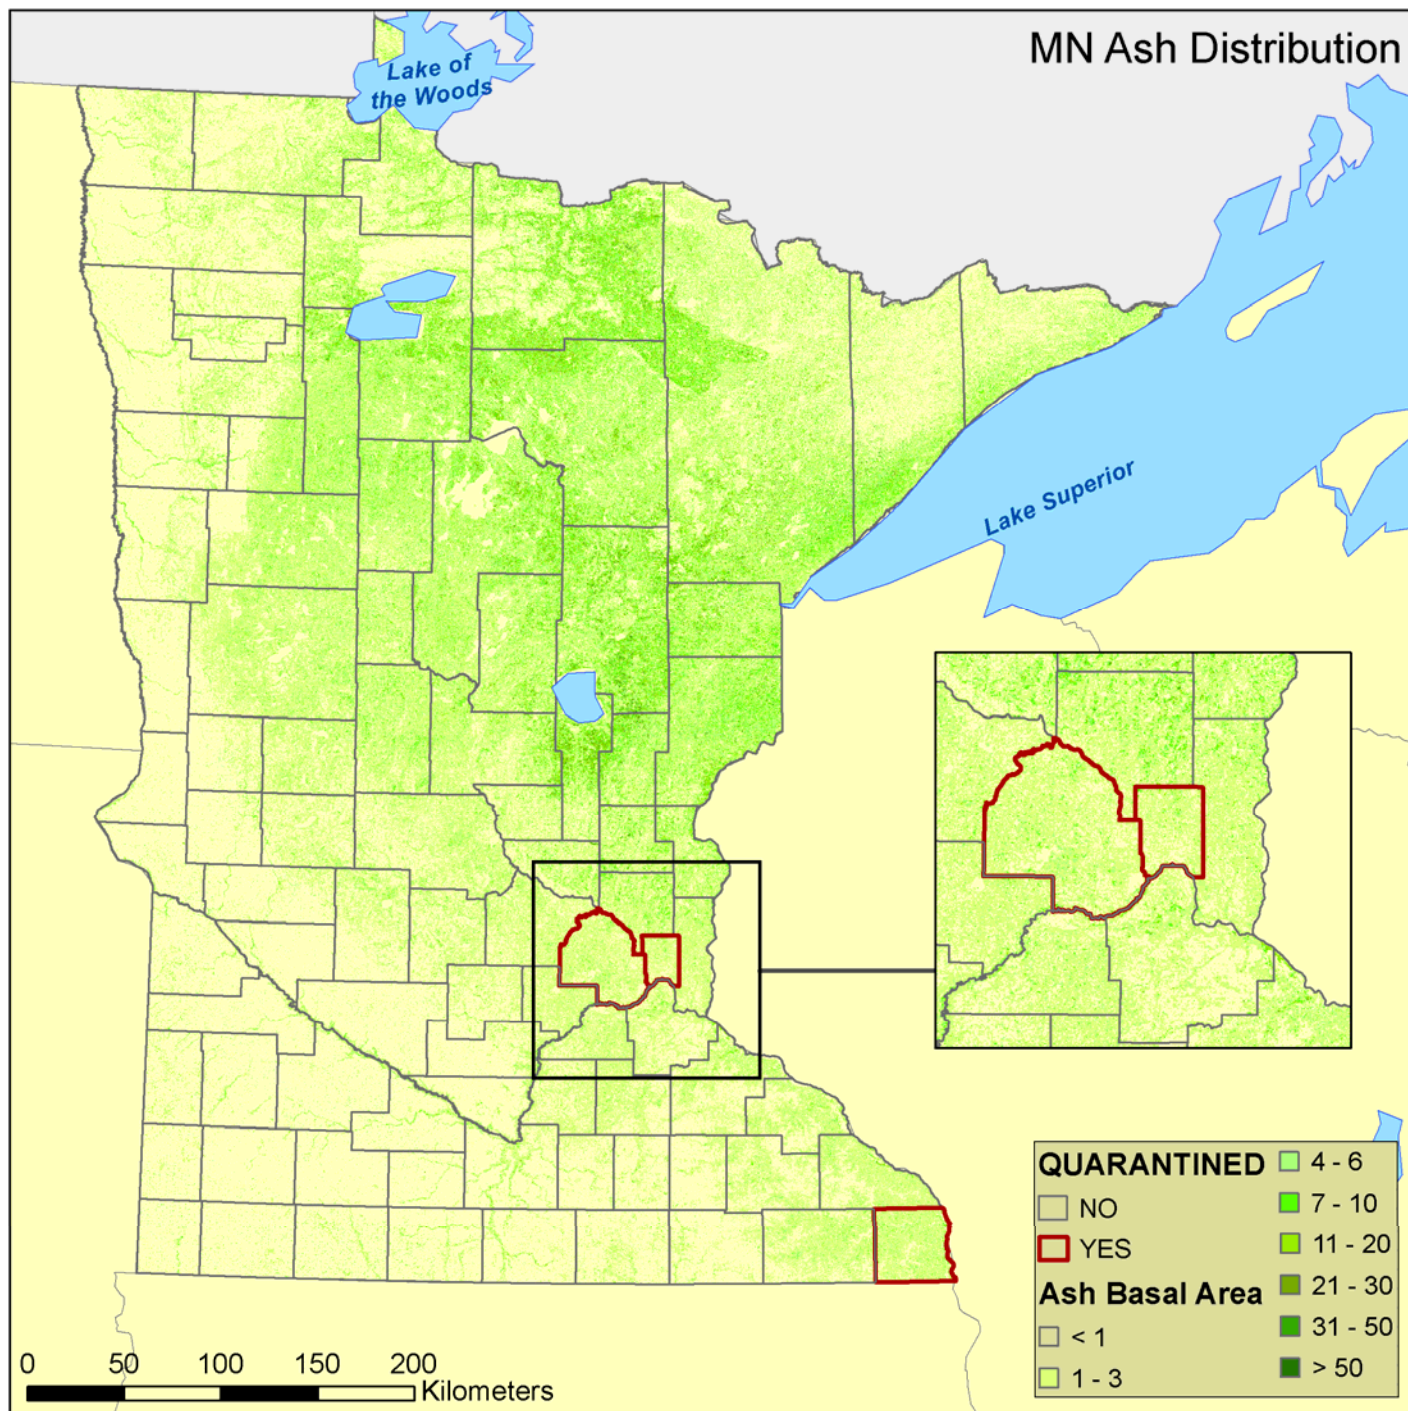

- Aspects of our model results are artifacts of our “EAB-positive-location” influenced weighting scheme - problematic to validate.
- However, we used a robust statistical technique, RF to test the importance & give insights for weighting the ride model.
- Created an imputed map of risk in Ohio based just on the RF model and compared it to EAB-SHIFT – shows that our “2-components model” is better than a robust statistical model for predicting EAB positives.
- We hope that our model is of practical use to on-the-ground folks trying to deal with this menace based on uncertain information.
- Our model helps locate areas of high risk and allow managers to focus on areas where the infestation is most likely to occur.
- May give state/county agencies some basis to decide where to locate traps or detection trees.
- Could help researchers in sample design.
- Will validate/un-validate itself over the years as EAB inevitably spreads across the U.S!

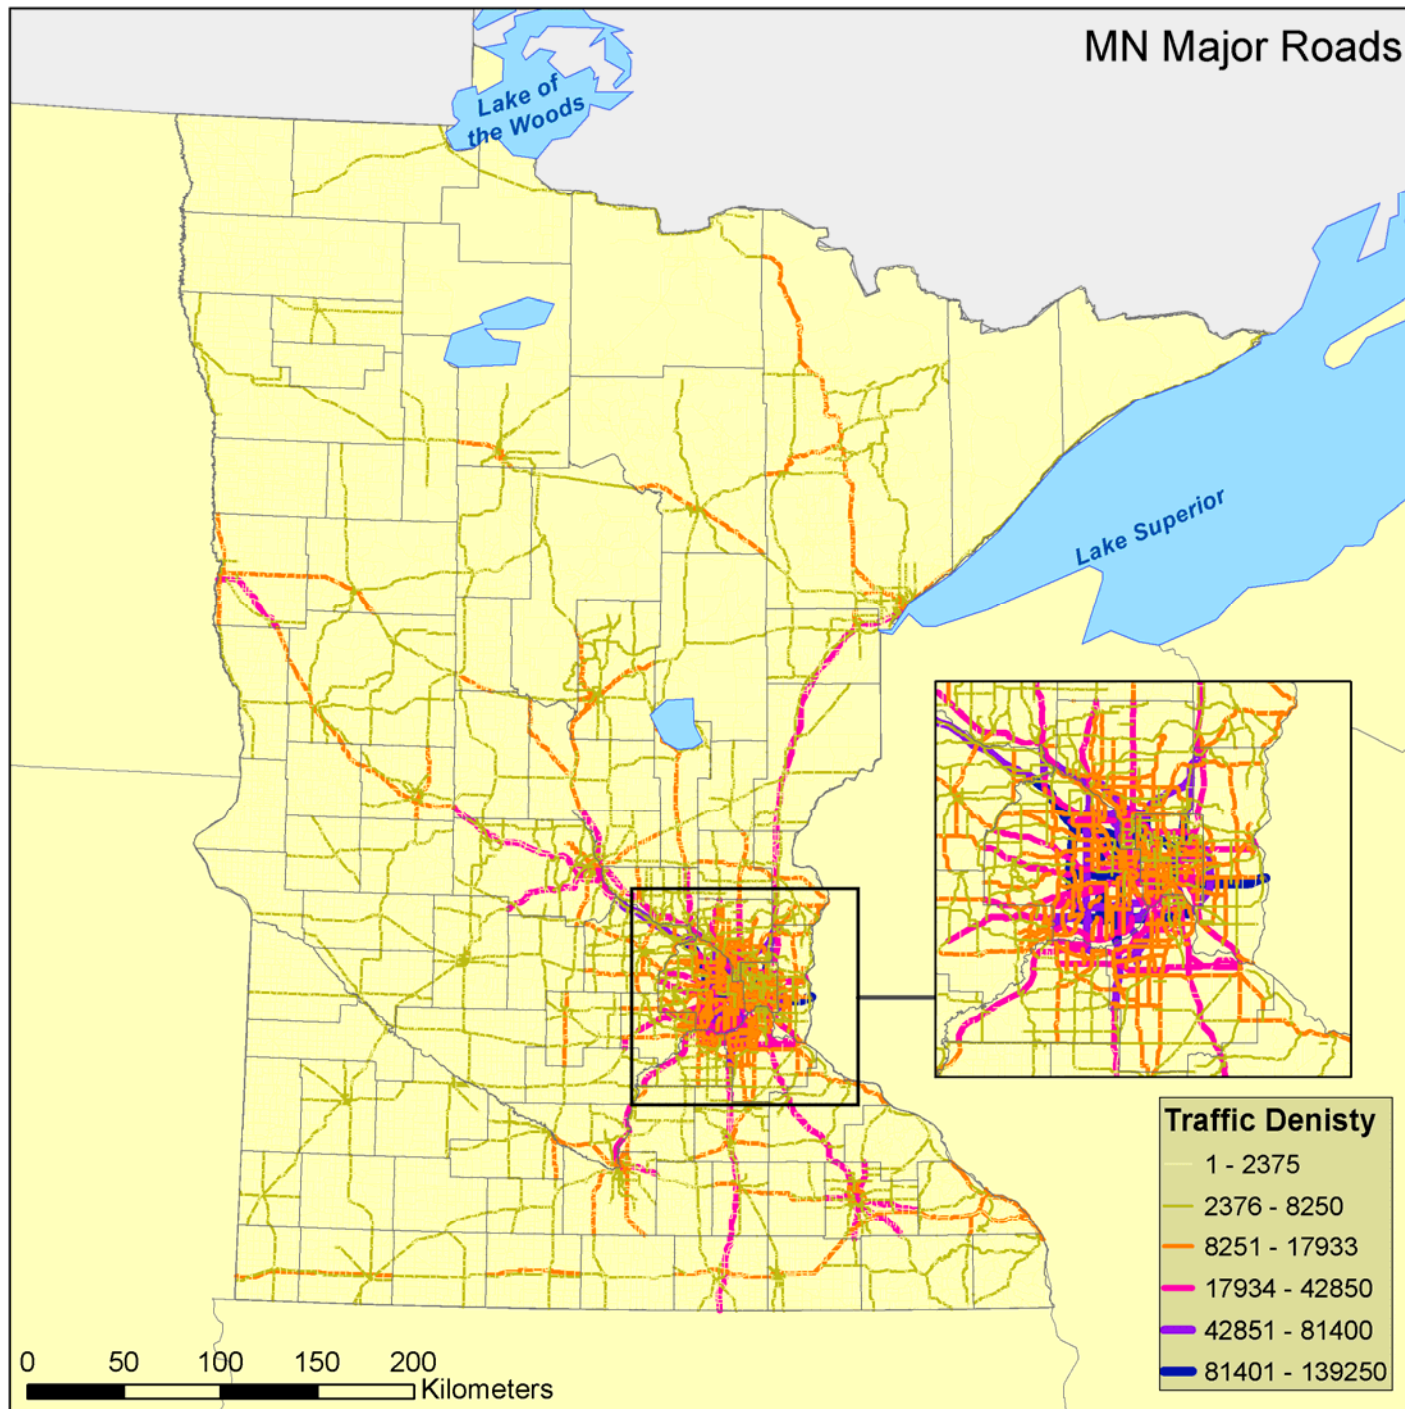

Model building for Minnesota

- ✿ Input data generated by Minnesota DNR, primarily Dennis Kepler
- ✿ We plan to run the model this summer
- ✿ The following slides display some of the data

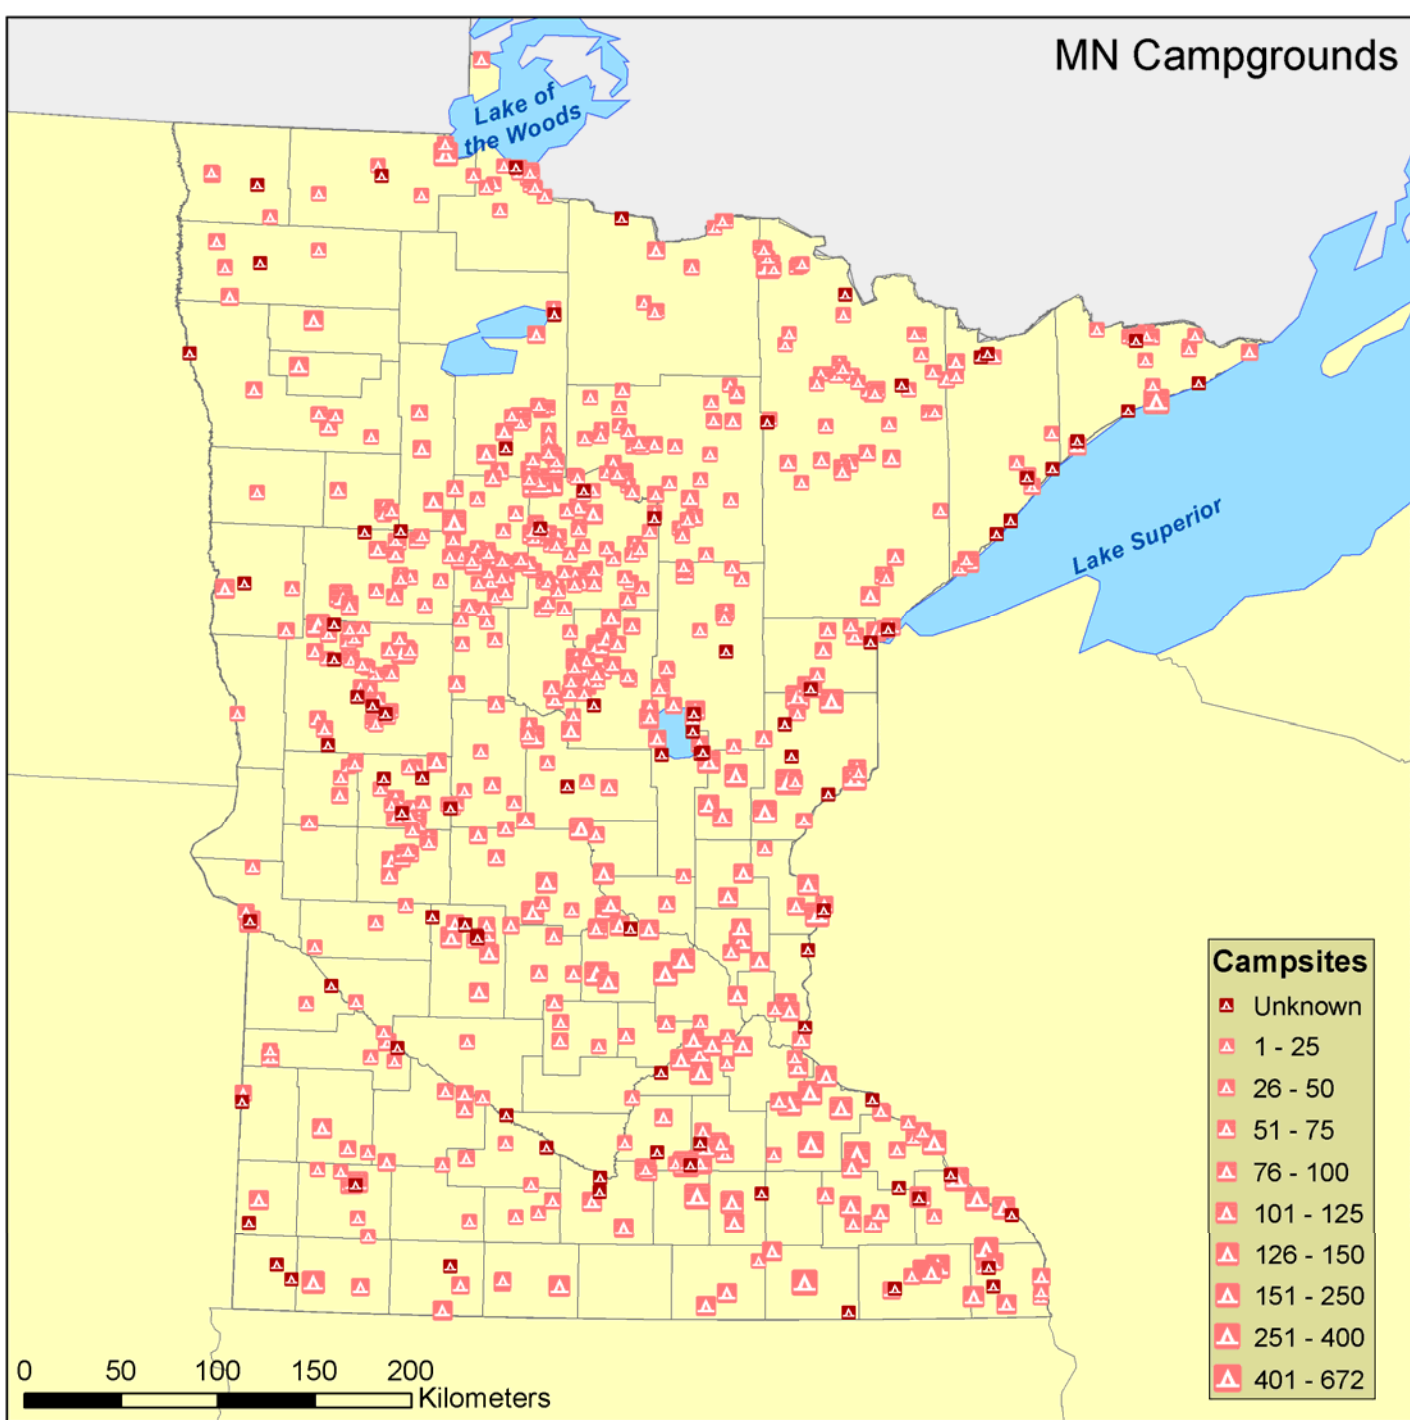

MN Ash Distribution

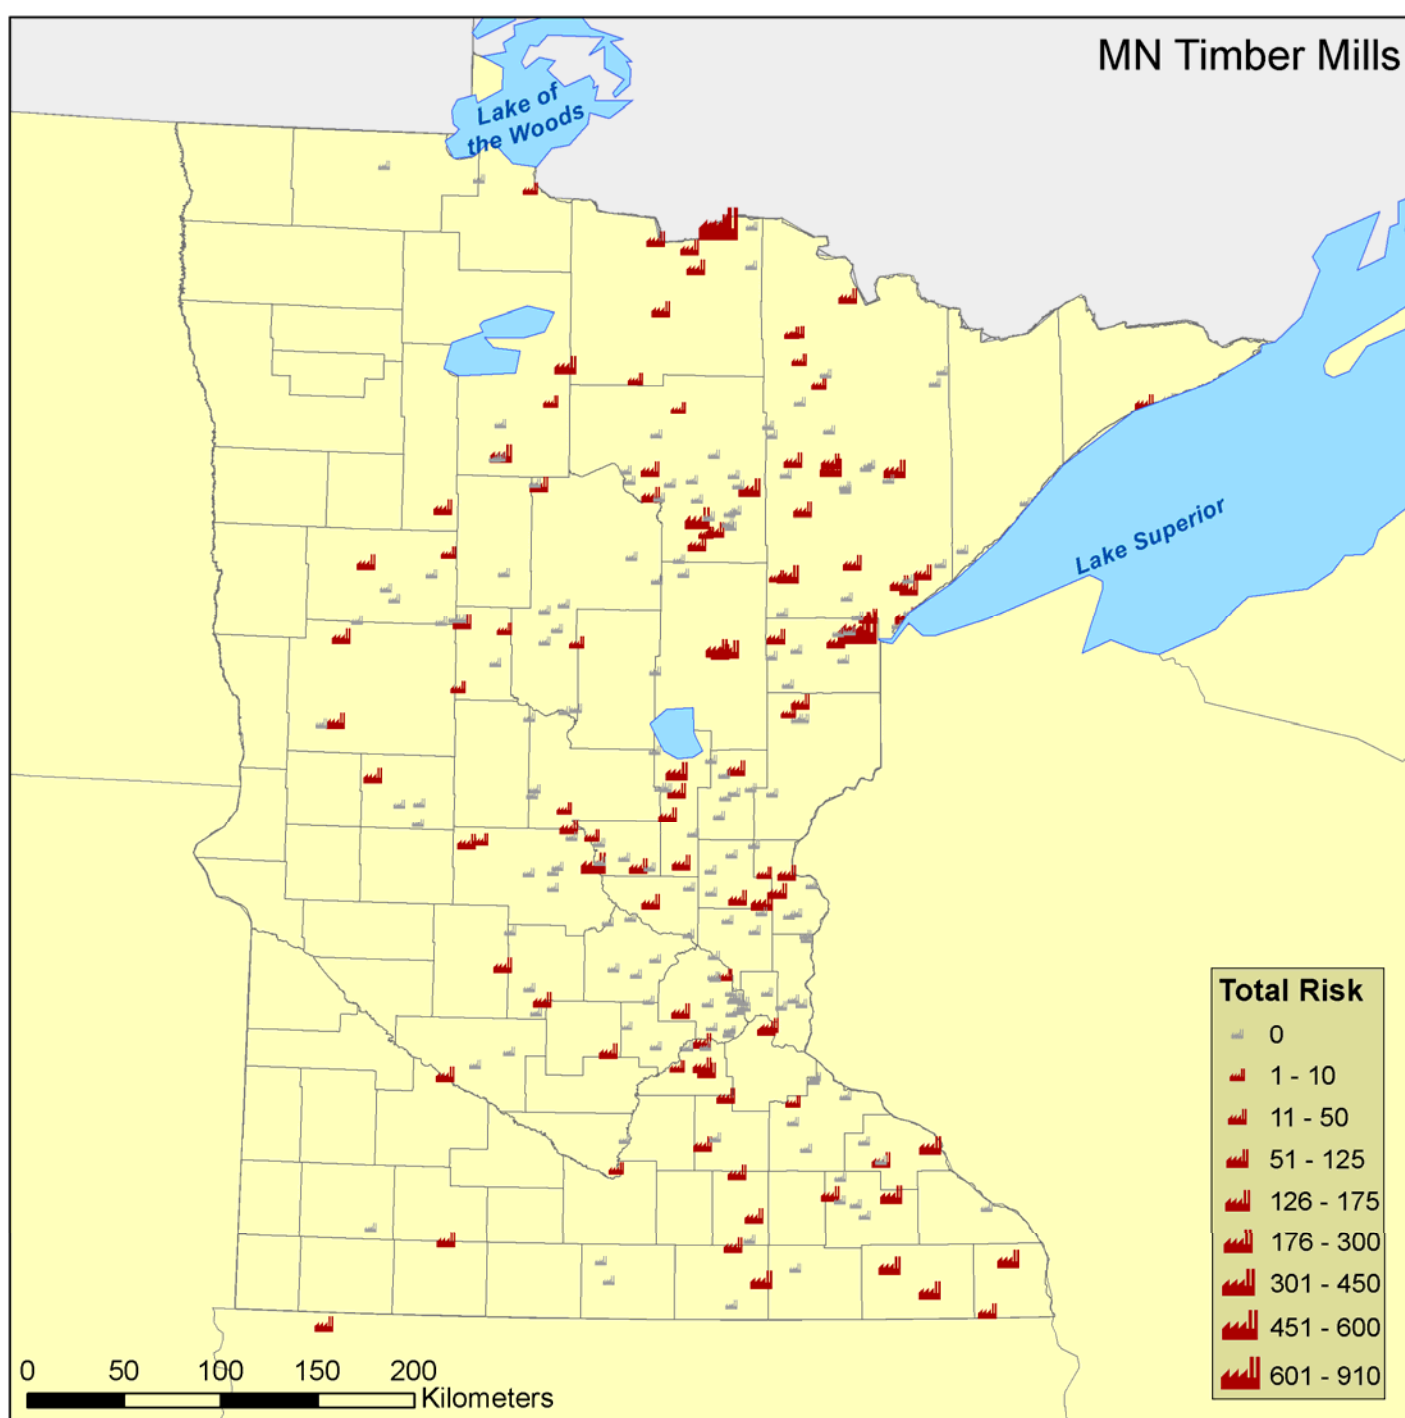

MN Major Roads

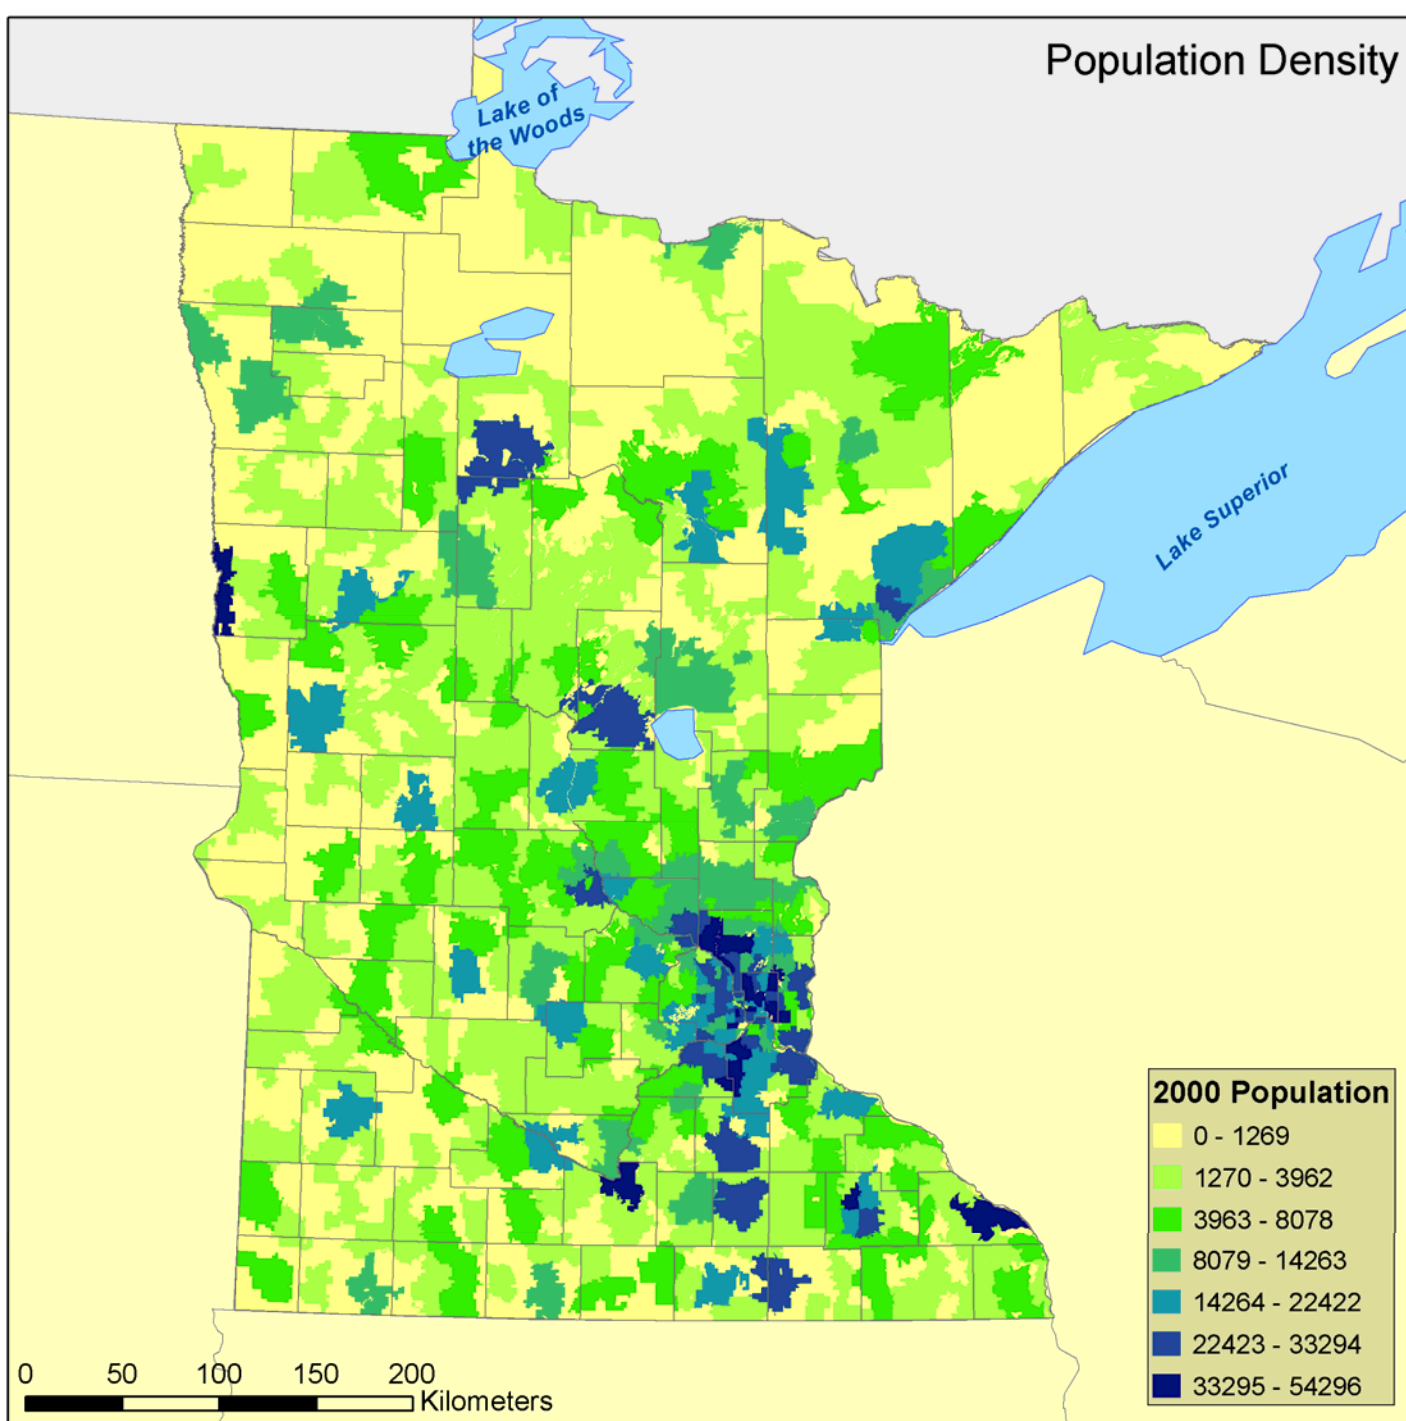

MN Campgrounds

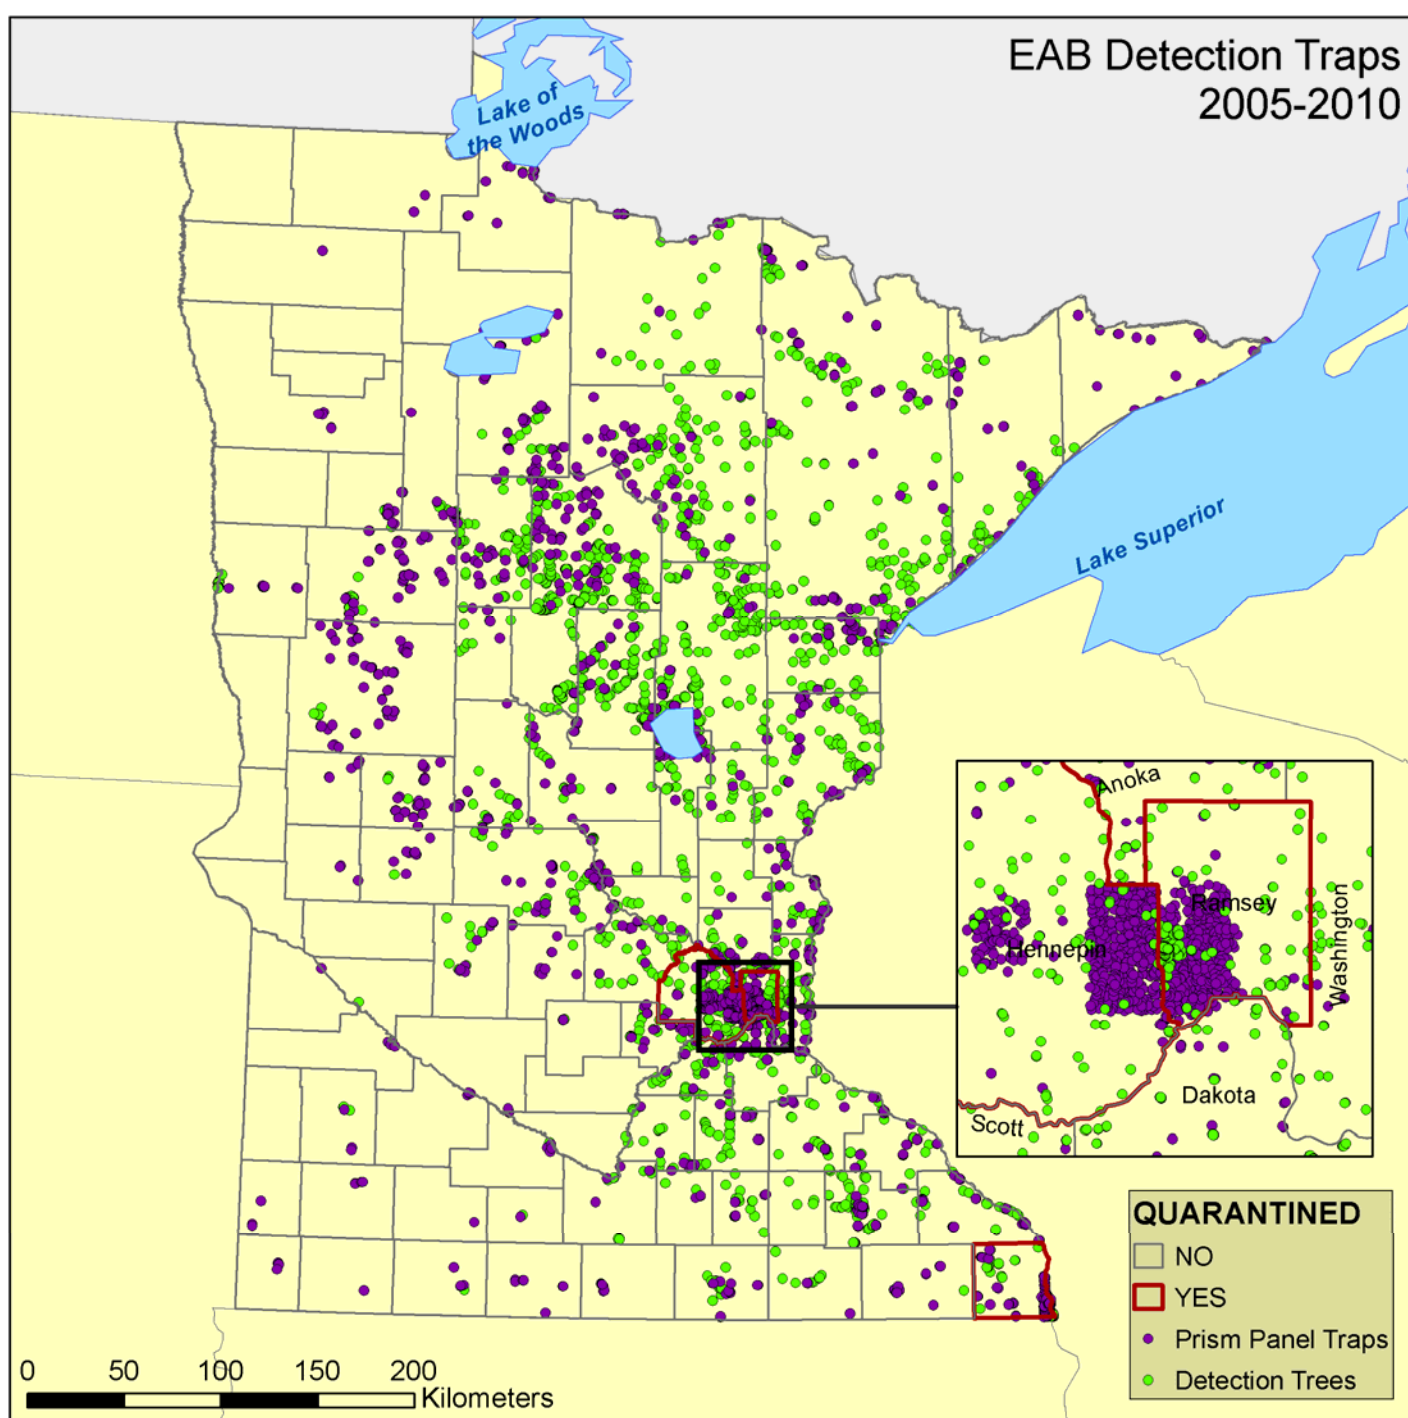

MN Timber Mills

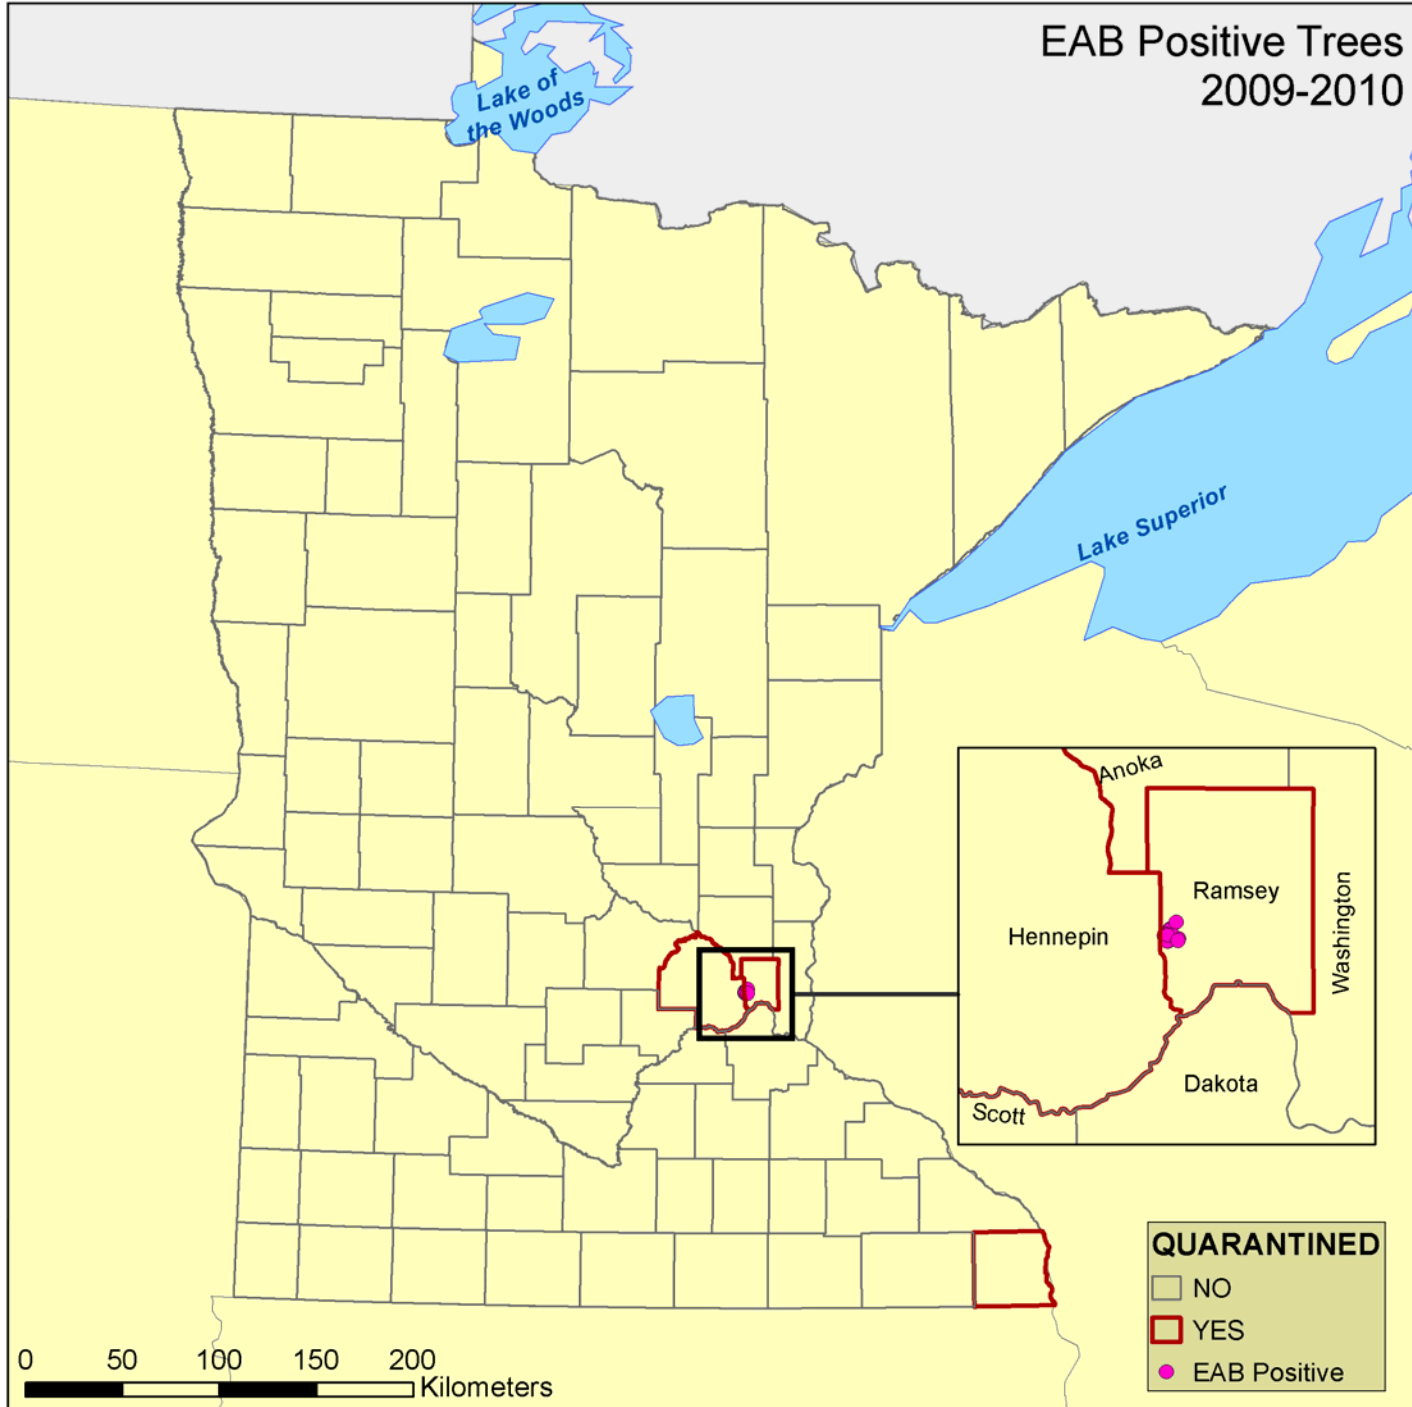

Population Density

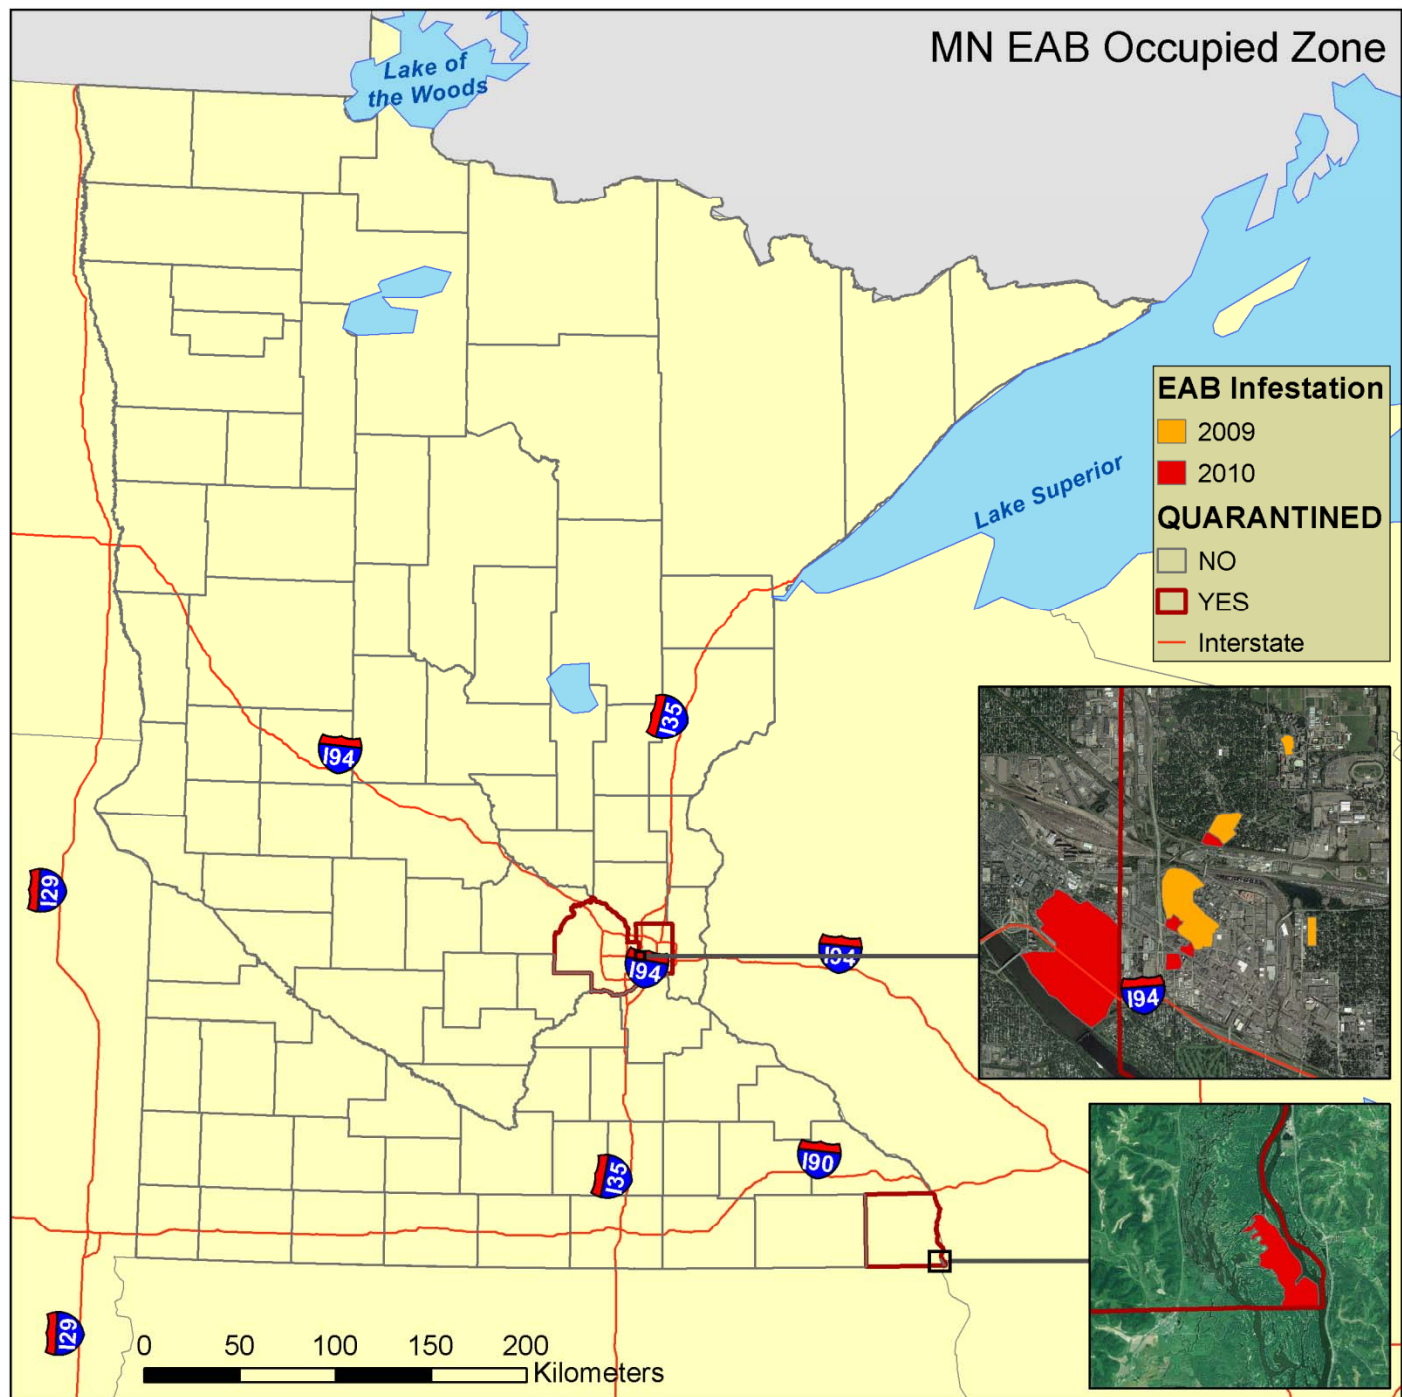

EAB Detection Traps 2005-2010

EAB Positive Trees 2009-2010

MN EAB Occupied Zone

We welcome your ideas & suggestions!

Thank you!
